60 **In Taiwan, Omicron BA.2.3.7 Variant has emerged and persisted in dominance**

61 **as a cause of community outbreaks**

62 **Running Title: Prevalent SARS-CoV-2 Variant of Asia**

63 **Keywords: SARS-CoV-2, Omicron variant, NGS**

64

65 **ABSTRACT**

66 Using high-throughput sequencing of the SARS-CoV-2 genome, we have analyzed
67 2405 PCR-positive swab samples from 2339 individuals and identified the Omicron
68 BA.2.3.7 variant as a major lineage of the recent community outbreak in Taiwan.
69 Since April 2022, a series of new waves of Omicron cases have surfaced in Taiwan
70 and spread throughout the island. We conducted genomic surveillance with a high
71 success rate and have submitted 1966 full-length Omicron sequences to GISAID. This
72 has permitted identification of signature amino acid changes (ORF1a:L631F, S:K97E,
73 N:M322I) in 1584 (80.6%) of the translated SARS-CoV-2 sequences. The newly
74 established BA.2.3.7 lineage, which is relatively common in Asian countries, is now
75 persistently present in Taiwan. By June 2022 this dominant strain had established a
76 substantial existence in the sequence pool, resulting in additional mutations. The rapid
77 spread and expansion of the Omicron BA.2.3.7 lineage in Asia has had an important
78 socioeconomic impact on health policy.

79

80 INTRODUCTION

81 The coronavirus disease 2019 (COVID-19) pandemic, caused by severe acute
82 respiratory syndrome coronavirus 2 (SARS-CoV-2), originated in the People's
83 Republic of China (PRC) in late 2019, probably in the city of Wuhan(1-3). The
84 outbreak of this unusual respiratory disease led to a wide variety of different
85 responses by various countries across the world(4-7). The response of Taiwan was
86 rapid and based on both its proximity to the PRC and its experiences during the SARS
87 pandemic almost two decades earlier(6, 8, 9). The introduction of almost complete
88 travel restrictions on incoming air and sea passengers, long compulsory quarantine
89 periods for the few residents who were allowed to enter Taiwan and a very wide
90 acceptance by the population of social distancing, temperature checks, mask wearing,
91 etc., in all social situations, meant that, unlike many other countries, the entry of the
92 COVID-19 pandemic was delayed significantly(6, 10, 11). Until April 2022, there
93 were only limited breakthroughs, all of which were quickly contained; these were
94 associated with cases detected among the very limited number of travelers entering
95 the country who were hospitalized on being identified as being infected and airline
96 crews. Hence, Taiwan provides a unique opportunity to explore what happened when

97 the Omicron variant evaded the controls put in place by the Taiwan government and
98 began to spread through the country's population. The Taiwanese population had not
99 been exposed on a large scale to any of the virus variants before Omicron and by the
100 time the virus began to spread widely in March/April 2022, a significant percentage of
101 the population had been vaccinated. As a result, an in-depth exploration of the virus
102 using high-throughput sequencing as it spread provides new insights into how a novel
103 pandemic virus enters and spreads in a mostly naïve population. In the current study,
104 we have collected a large numbers of Omicron sequences from domestic cases and
105 applied phylogenetic analysis to gain insights about the introduction of the new
106 Omicron variants into Taiwan and the evolution of genomic sequences during rapid
107 expansion of the viral pool over a time period of 15 weeks (from February 22nd to
108 June 6th).

109

110

111

112

113

114 **METHODS**

115 We applied Illumina COVIDSeq amplicon sequencing technology to the whole-
116 genome analysis of SARS-CoV-2(12). RNA was extracted from virus-inactivated
117 swab samples. Complementary DNA synthesis was carried out using the reagents
118 provided by the manufacturer, by which the SARS-CoV-2 genome underwent reverse
119 transcription and was then amplified in 98 overlapping amplicons, together with
120 appropriate human controls. In the finally optimized procedure, we processed 384
121 samples at a time, and analyzed the pooled libraries on a single lane of the S4 chip
122 using the NovaSeq6000 instrument.

124 **Patients and RNA extraction**

125 Cases were recruited from National Taiwan University Hospital Hsinchu Branch
126 (NTU-HCH). Samples for RNA extraction were collected in 3 mL sterile viral
127 transport medium (VTM) tubes and consisted of 2405 nasopharyngeal swabs
128 belonging to 2339 patients. RNA was prepared by automated extraction using the
129 TAINBead Nucleic Acid Extraction Kit REF M665A46 (Taiwan Advanced Nanotech

130 Inc.) and the QIAasymphony SP protocol (QIAGEN). This study was reviewed and
131 approved by the Research Ethics Committee (110-110-E) of NTU-HCH.

132

133 **COVIDseq**

134 We carried out the sequencing using Illumina COVIDSeq Test kits (RUO version)
135 according to the manufacturer's instructions. The workflow consists the following
136 steps: cDNA synthesis, then virus target amplification using V3 nCov-2019 primers,
137 followed by library preparation and library pooling. Subsequently, 98 targets on
138 SARS-CoV-2 and 11 human fragments, which acted as controls, were analyzed on a
139 NovaSeq 6000 instrument by using 2x151-bp paired-end reads. Next, we used
140 Illumina DRAGEN COVID Lineage app version 3.5.9 (base on pangolin 4.1.2
141 pangolin-data 1.12 and NextClade 1.11.0) in the BaseSpace Sequence Hub for rapid
142 analysis.

143

144 **Phylogenetic analysis**

145 A set of 1966 NTU-HCH sequences were deposited to the Global Initiative on
146 Sharing All Influenza Data (GISAID)(13) with the following epi accession numbers:

147 EPI_ISL_14192849 to EPI_ISL_14192840, EPI_ISL_14191496 to
148 EPI_ISL_14191488, EPI_ISL_14191320 to EPI_ISL_14190364, and
149 EPI_ISL_14190353 to EPI_ISL_14189364. To investigate the global transmission,
150 249 BA.2.3.7, 282 global, and 403 additional sequences from Taiwanese were
151 retrieved from GISAID as of July 2022. A total of 2847 sequences including 1966
152 from NTU-HCH and 881 reference sequences (**Supplementary Data: S Table 1**) that
153 had met the quality standard were used for the analysis. The phylogenetic tree was
154 constructed using Nextstrain CLI (command-line interface) (version 3.2.5)(14) and
155 visualized with Auspice (<https://auspice.us/>).

156

157

158

159

160 **RESULTS**

161 As shown in Figure 1, very few COVID-19 cases occurred in Taiwan during
162 2020 and 2021. Clustered infections were reported in May and June 2021, mainly in
163 northern Taiwan. Even at their peak, only hundreds of positive cases were recorded by
164 Taiwan's Centers for Disease Control (CDC) (**Insert of Figure 1**). At the beginning of
165 2022, a number of Omicron infection clusters were noted first in northern Taiwan, and
166 very soon new cases began to exceed fifty thousand per day with the outbreaks
167 affected the entire country (<https://nidss.cdc.gov.tw/nidss/disease?id=19CoV>). To
168 gain insights about the community transmission of the infection and to monitor viral
169 evolution, we established a genomic surveillance program at National Taiwan
170 University Hospital Hsinchu Branch (NTU-HCH) and conducted whole-genome
171 sequencing using left-over nasal swab samples that had been detected by PCR to be
172 positive.

174 **Pilot phase of genomic surveillance for COVID-19**

175 In order to conduct genomic surveillance of SARS-CoV-2, we have adopted the
176 COVIDSeq procedure (Illumina). Initially we used the ultrashort read (2 x 51 bp)

177 approach in order to obtain real-time information. Later we modified the procedure
178 and applied the libraries created from 384 samples onto a single lane of an Illumina
179 S4 chip, which typically was able to generate over 700 Gb data. In principle, this
180 sequencing depth should give almost 60,000-fold coverage of the virus' 29,932 bp
181 genome. During the pilot phase when we were establishing the genomic surveillance
182 program, we analyzed 293 samples from 228 patients in three batches (**Figure 1**,
183 batches 1-3), and most of these cases had been collected during 2021 from three
184 hospitals in northern Taiwan (**Supplementary Data, S Table 2**). From this limited
185 number of cases that were associated with various small community outbreaks in
186 Taiwan (Insert of Figure 1), we found that these sequences mainly belonged to the
187 Alpha lineage (B.1.1.7), and they included sequences from a cluster infection
188 affecting a factory near our hospital.

190 **Serial Investigation of SARS-CoV-2 in a medical center**

191 Beginning in 2022, we gradually expand the application of the established
192 genomic surveillance protocol to conduct a series of investigation on samples
193 collected at NTU-HCH. From end of February to beginning of June, there was a huge

194 surge in cases due to infection with Omicron variants of SARS-CoV-2 (**Figure 1**).

195 These samples became the major source providing the genome sequences for the

196 current study. There were in total 2112 PCR-positive swab lysates analyzed and these

197 consisted of one set of 192 samples (batch 4) and five sets of 384 samples (batch 5)

198 (**Figure 1 and Supplementary Data, S Table 2**). Except for one case, all subjects

199 provided one PCR+ sample for the viral genome analysis. Clinical information on the

200 1920 subjects recruited for batch 5 at NTU-HCH is readily available, and the general

201 characteristics of these COVID-19 infected individuals are shown in Table 1. Almost

202 an equal number of males and females were recruited, and, among them, 103 and 430

203 individuals had an age below 2 and an age between 2 and 20, respectively. Six

204 hundred and eight (31.7%) of the patients had been admitted to NTU-HCH for

205 treatment, while 83 (4.3%) of them were symptom free. As expected, the young age

206 group (below 2 years) and the old age group (over 60 years) were found to form larger

207 proportion of the hospitalized patients.

208

209 **Success rate when calling a variant**

210 The established protocol was highly efficient at generating a large amount of
211 genomic information that allowed the identification of the viral lineage of each
212 individual sample; furthermore, it also allowed reliable genome assembly for
213 subsequent phylogenetic analysis. For practical purposes, we defined a successful call
214 if the DRAGEN COVID Lineage software (v3.5.9) returned identifiable lineage
215 information for a sample. Combining the pilot phase (batches 1-2 of 2021) and the
216 serial investigation phase (batches 3-5 of 2022), in total we have performed 2405
217 genomic analyses and determined SARS-CoV-2 lineage for 2368 individuals (success
218 rate, 98.5 %). Of the samples that failed to generate reliable sequence, the majority
219 had a Ct value of 29 or greater. Only four samples with a Ct value of 28 or less failed
220 to generate a reliable lineage information. Thus, the overall success rate of calling a
221 lineage was largely determined by the Ct value, and perhaps, to some extent, the
222 storage time and condition of the sample. For the last five batches of 384 samples
223 each, the majority were processed within 4 weeks and had Ct values of 28 or less;
224 these had a success rate of 99.7% (1914/1920).

225

226 **GISAID submission**

227 Specifically, we have only submitted genomic data to GISAID on those
228 sequences that had a greater than 98% coverage of the 29903 bp SARS-CoV-2 target
229 genome. The same set of high-quality sequences were used for tracking the signature
230 mutations in the viral samples (**Figure 2**) and for phylogenetic analysis (**Figure 3**).
231 Overall, 2424 samples of all five batches generated 2024 sequences (84.2% pass rate)
232 that met the above criterion. For the last five batches of 384 samples, 1720 of the
233 1920 sequences was selected (89.6 % pass rate) for GISAID submission
234 (**Supplementary Data, S Table 3**). These samples were obtained between April 26th
235 and June 6th, during the peak of the present Omicron outbreak.

237 **Signature mutations of the BA2.3.7 lineage**

238 We analyzed the assembled viral genome sequences and searched for significant
239 amino acid changes in the Omicron samples collected in 2022 (**Supplementary Data,**
240 **S Table 4**). Comparing the later three data sets (batch 3 to batch 5), we discovered
241 that three amino acid changes (ORF1a:L631F, S:K97E, N:M322I) occurred only after
242 the fourth sequencing batch. All the Batch 3 isolates belonged to the BA.1 or BA.2
243 classification. This suggests that the rapid increase of cases in Taiwan in April and

244 May, from previously zero cases per day, to almost reaching a hundred thousand per
245 day, came from a strain that was evolving in Taiwan and showed either advantageous
246 viral replication or advantageous transmissibility. The percentage of sequences
247 containing the signatures progressed steadily from 62 % in batch 4 to 85% in batch 5.

248 Of the three signature mutations shown in Figure 2A, the L631F mutation in
249 ORF1a and K97E mutation in the S protein are located within nsp2 and the N-
250 terminal domain of S1, respectively. The third signature mutant of variant BA.2.3.7 is
251 a methionine to isoleucine substitution at amino acid 322 (M322I) of the N protein.
252 Both methionine and isoleucine are nonpolar amino acids. Previous reports have
253 suggested that M322I could bring about a slight decrease in N protein thermal
254 stability(15) and might affect the host immune response to COVID-19 viral
255 infection(16).

256

257 **Evolution of the Omicron BA.2.3.7 lineage**

258 Serial investigation of the collected samples by whole-genome sequencing allowed us
259 to monitor the continuous evolution of the Omicron BA.2.3.7 lineage, as it became
260 the dominant strain of Taiwan (**Figure 2B**). In the 15-week period of February 22nd to

261 June 6th, there has been a sharp increase of the Omicron variant BA.2.3.7 at week 5
262 (March 23th to March 29th) and the proportion of this variant remained at over 80%
263 level for ten weeks (**Figure 2B**). Of note, a steady increase of sequences positive for
264 S:G1251V started at week 6 and reached plateau at week 10 (April 26th–May 2nd). By
265 contrast, over the time period week 10 to week 15, the percentage of ORF1a:T3224A
266 decreased, while that of ORF1a:A591V and ORF1a:V3683I increased, suggesting that
267 these sublineages might have different transmission efficiencies. Moreover, a new
268 mutation, ORF1a: I1091T, was detected during week 13 and the incidence had
269 increased substantially by weeks 14-15.

270

271 **Phylogenetics of the SARS-CoV-2 isolates**

272 To construct the framework of the phylogenetic tree, first we took 1966 genome
273 sequences from this study and analyzed them in the global context of 872 GISAID
274 reference sequences (**Figure 3A**). On this basis, we then zoomed in and compared the
275 1584 Omicron sequences of the current study against the 228 Omicron BA.2.3.7
276 strains from the GISAID database (**Figure 3B**). These sequences had been reported

277 from 21 countries, including 51 from Taiwan (**Supplementary Data, S Table 1 and**
278 **5**).

279 We interpreted the phylogenetic analysis in the context of Pango-dynamic
280 nomenclature system(16). On May 16th, an issue was raised regarding a BA.2.3
281 sublineage with S:K97E ([https://github.com/cov-lineages/pango-](https://github.com/cov-lineages/pango-designation/issues/643)
282 [designation/issues/643](https://github.com/cov-lineages/pango-designation/issues/643)). It was suggested that “this new sublineage” might have a
283 very high prevalence in Taiwan, and it might be descended from a mainly Vietnamese
284 branch with ORF1a:L631F and N:M322I. Later, BA.2.3.7 was designated, and as of
285 July 22nd, there have been 222 sequences in the BA.2.3.7 lineage detected since it was
286 identified on February 27th (Lineage Report, [https://outbreak.info/situation-](https://outbreak.info/situation-reports?pango=BA.2.3.7)
287 [reports?pango=BA.2.3.7](https://outbreak.info/situation-reports?pango=BA.2.3.7)).

288 It is evident that this novel lineage BA.2.3.7 with three amino acid changes
289 (ORF1a:L631F, ORF1a:S:K97E, and N:M322I) was circulating dominantly in
290 Taiwan over the study period (**Figure 3B**, BA.2.3.7 branch, marked in red). Notably,
291 the first BA.2.3.7 strain identified in the epidemic in Taiwan was collected on March
292 27th, 2022, and, since that point, we have already detected several genomic changes of
293 this new Omicron lineage. For example, a new mutation, G1251V (**Figure 3B**,

294 marked in green) in Spike protein, was detected from April onwards, and this
295 particular circulating lineage has rapidly spread across Taiwan.

296

297 **Persistent dominance of Omicron BA.2.3.7 lineage**

298 While this paper was in preparation, we became aware that a number of viral
299 sequences with the same signature mutations had been reported from Taiwan
300 ([https://outbreak.info/situation-reports?pango=BA.2.3.7&loc=USA&loc=USA_US-
301 CA&loc=TWN&selected=TWN&overlay=false](https://outbreak.info/situation-reports?pango=BA.2.3.7&loc=USA&loc=USA_US-CA&loc=TWN&selected=TWN&overlay=false)). Even though the number was
302 relatively small (51 cases) as compared to our serial investigation at a medical center,
303 the four locations in Taiwan of the reported cases are different from our collection
304 point at the hospital, indicating that this new lineage was detectable broadly across
305 Taiwan. Based on this distribution, it is very likely that the BA.2.3.7 lineage is now
306 the dominant variant throughout Taiwan.

307 Notably, over the same time period, other Asia Pacific countries (Hong
308 Kong/PRC, Indonesia, Singapore, Vietnam, Japan, Thailand, Philippines, New
309 Zealand, and Malaysia) have also reported significant cumulative prevalence of the
310 BA.2.3.7 variant (**Supplementary Data, S Table 5**). Among the 44 Omicron

311 BA.2.3.7 strains reported from Japan, two of the affected individuals had travel
312 history to Vietnam and 41 to Taiwan, suggesting significant silent outward
313 transmission events from Taiwan. By way of contrast, BA.2.3.7 forms less than 0.5%
314 of the sequences reported in either California, USA, or globally.

328 **DISCUSSION**

329 In the Western world, where there have been less restrictions on travel and
330 people have shown poorer adherence to wearing facial masks, COVID-19 outbreaks
331 have occurred in several waves as SARS-CoV-2 evolved. These seem to have been,
332 originally associated in many cases with persistent infections in immunocompromized
333 patients, they then, have adapted to the human populations in the various countries.
334 From 2020 to 2022, there have been several changes in the dominant viral lineages,
335 with new more transmissible strains replacing previous prevailing lineages.

336 The entry of the Omicron variant into Taiwan in early 2022 was unexpected as
337 the track-and-trace system put in place from January 2020 onwards had been very
338 successful with only a limited number of community outbreaks in 2021, each of
339 which was traced to source and controlled. In early 2022, vaccination against SARS-
340 CoV-2 in Taiwan had reached nearly 90 % (for at least one dose) of the 23 million
341 population (covid-19.nchc.org.tw; Taiwan CDC data). This population is highly
342 urbanized with about a quarter of the population living in the Greater Taipei Area. So
343 as Omicron began to spread, it was within a naïve but vaccinated population.
344 Taiwanese have shown high levels of compliance with social distancing and mask

345 wearing, so the spread of Omicron was in a unique environment, unlike Europe, the
346 USA and Canada, South America, Africa or even New Zealand. The Omicron variants
347 detected in Taiwan are likely to be those that have evolved to escape the specific
348 conditions found in Asia; this means that these “Asian” strains have undergone
349 selection such that they are highly transmissible, produce silent infections without
350 symptoms and have the ability to escape the vaccines used in Taiwan. In conjunction
351 with these phenotypes, another possibility is that the ethnicity of Taiwan's population
352 may have played a role. There is believed to have been a coronavirus outbreak in Asia
353 more than 20,000 years ago (17) and the selection imposed by this may have changed
354 the genetics of the Taiwan population.

355 The failure to control the 2022 Omicron outbreak may rest on the fact that there
356 were multiple and almost simultaneous entry of different SARS-CoV-2 variants,
357 unlike earlier breakthrough events, and that many of these infections were silent. The
358 often-silent nature of Omicron would have allowed the development of community
359 outbreaks beyond the available control measures. Notwithstanding the possibility of
360 multiple entry events into Taiwan of the BA.2.3-related variants, there seems to have
361 significant diversity of the viral strains circulating in Taiwan. Importantly, the large

362 numbers of quality sequences we have collected contribute to the identification of
363 some less frequent mutations (ORF1a: A591V, ORF1a: T3224A, ORF1a: V3683I)
364 within the BA.2.3.7 lineage (**Supplementary Data, S Table 4**). It is likely that further
365 evolution of the BA.2.3.7 lineage in Taiwan has occurred (**Figure 3**), as new groups
366 of the SARS-CoV-2 sequences are becoming evident. Based on the phylogeny and the
367 signature mutations, we have divided the BA.2.3.7 isolates into at least five genotypic
368 groups, each with clearly defined sequence features (**Figure 3**).

369 The emergence of Omicron BA.2.3.7 in Asia is remarkable. While there is no
370 reliable genomic data from the early cases arising from Malaysia and Vietnam, our
371 phylogenetic analysis and the metadata from GISAID indicate that travelling between
372 Asian countries have contributed to the rapid spread of this unique Omicron lineage in
373 this region. The majority of Omicron BA.2.3.7 cases reported from Japan in May
374 2022 had travel history to Taiwan, and the GISAID sequences clearly indicated that
375 they were related to two branches of the phylogenetic tree (**Figure 3B**), one with
376 S:G1251V mutation and one without.

377

378 In conclusion, our genomic dataset is uniquely valuable for understanding how a
379 major COVID-19 outbreak occurred in a naïve and vaccinated population in Taiwan
380 with a very limited number of entry events. As Asian countries began to move from
381 zero tolerance to gradual opening policy, continued surveillance of SARS-CoV-2
382 using NGS is important. Early detection of significant viral evolution in the endemic
383 areas will minimize any disruption due to a new variant.

447 **ACKNOWLEDGEMENTS**

448 This work was supported by Ministry of Health and Welfare of Taiwan (MOHW110-
449 TDU-C-222-000010) to S.F.T., by the Research Center for Emerging Viral Infections
450 from The Featured Areas Research Center Program within the framework of the
451 Higher Education Sprout Project by the Ministry of Education (MOE) of Taiwan, the
452 National Science and Technology Council (NSTC), Taiwan (NSTC 111-2321-B-182-
453 001, 111-2634-F-182-001, and 111-2221-E-182-053-MY3), and the National Institute
454 Of Allergy And Infectious Diseases of the National Institutes of Health under Award
455 Number 5U01AI151698-02 to Y.N.G. and S.R.S. The authors wish to thank Y Henry
456 Sun and Hsiao-Hui Tso for critical reading of the manuscript, to Yi-Chun Tsai, Shuo-
457 Peng Chou, Jhen-Rong Huang, and Yuan-Yu You for sample collection and nucleic
458 acid preparation, to Tai-Yun Lin, Yu-Chen Huang and Chiao-Chan Wang for library
459 construction and sequencing operation.

460

461

462

463

464 **AUTHOR CONTRIBUTION**

465 P.L.S. collected clinical specimens and performed clinical data analysis. H.C.T.
466 performed COVIDseq and drafted the manuscript. Y.N.G. performed phylogenetic
467 analyses and drafted the manuscript. H.Y.S. performed mutation signature analyses
468 and manuscript preparation. R.K., Y.L.W., and W.J.C. interpreted data and prepared
469 the manuscript. L.Y.H. and H.Y.Y. collected clinical samples and performed nucleic
470 acid extraction. H.Y.K. and Y.C.H. managed clinical data and analyzed clinical data.
471 Y.F.L. and H.Y.W analyzed genomic data. C.C.C. collected samples and performed
472 viral analysis. T.W.C. collected samples and analyzed clinical data. K.M.L. and
473 C.G.H. established protocols and processed samples. S.R.S. performed the virology
474 study and functional analysis. C.C.W., C.J.Y., and S.F.T. managed the project and
475 prepared the manuscript.

481 About the Author

482 Dr. Shao is an assistant professor in Department of Laboratory Medicine and
483 Pediatrics, National Taiwan University College of Medicine, Taiwan. Her main
484 research interests include infectious disease, clinical virology, clinical microbiology,
485 and vaccines.

486
487 Dr. Tu is postdoctoral fellow in Institute of Molecular and Genomic Medicine,
488 National Health Research Institutes, Taiwan. Her research interests include cancer and
489 genomic research and NGS technology.

490
491 Dr. Gong is an assistant professor in Research Center for Emerging Viral Infections
492 and International Master Degree Program for Molecular Medicine in Emerging Viral
493 Infections, Chang Gung University, Taiwan. His research interests include
494 bioinformatics, phylogenetics, machine learning, and viral evolution.

495

Main Data

Table 1. Characteristics of the COVID-19 cases recruited for the current study

Figure 1. Community outbreaks of COVID-19 in Taiwan

Figure 2. Signature mutations of the Omicron BA.2.3.7 lineage

Figure 3. Phylogenetics of the SARS-CoV-2 isolates

Table 1. Characteristics of the COVID-19 cases recruited for the current study

Age (Yr)	0-2	2-20	20-60	Above 60	Total
Number	103	430	892	495	1920
Male	56 (54.4%)	250 (58.1%)	374 (41.9%)	258 (52.1%)	938 (48.9%)
Female	47 (45.6%)	180 (41.9%)	518 (58.1%)	237 (47.9%)	982 (51.1%)
Hospitalized	43 (41.7%)	35 (8.1%)	153 (17.2%)	377 (76.2%)	608 (31.7%)
Asymptomatic	0 (0%)	1 (0.2%)	66 (7.4%)	16 (3.2%)	83 (4.3%)

FIGURE 1: Community outbreaks of COVID-19 in Taiwan

This figure was constructed using the publicly available data of Taiwan CDC (<https://nidss.cdc.gov.tw/nndss/disease?id=19CoV>) to show the relative size of community outbreaks of COVID-19 in 2021 and 2022. Genomic surveillance was conducted in five batches to sequence the SARS-CoV-2 viral samples, and the height reflects the number of cases analyzed for each batch. The 2021 outbreak of Alpha lineage was relatively small and limited to cluster infection within New Taipei City (shown in the insert), while the outbreak of the Omicron lineage in April- June of 2022 exceeded 50,000 per day at peak level.

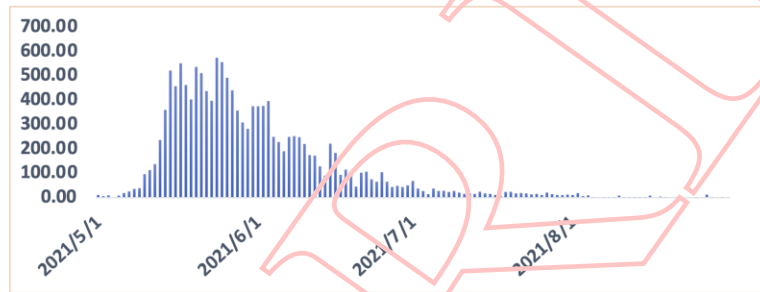

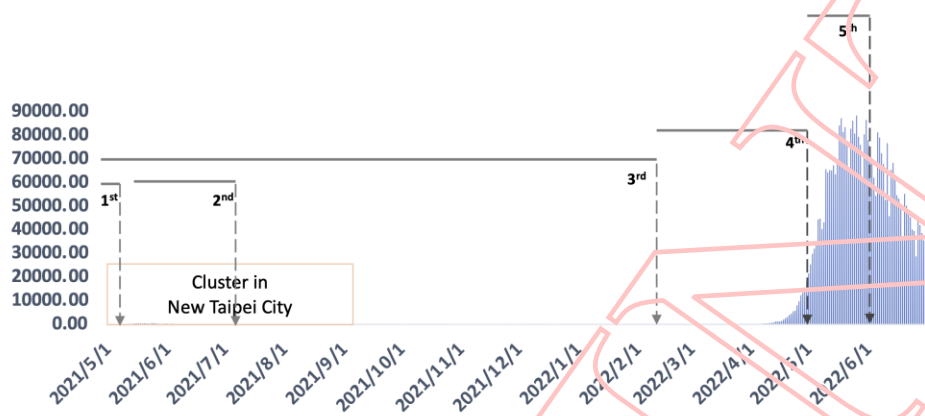

FIGURE 2: Signature mutations of the Omicron BA.2.3.7 lineage

2A. Mutations in the coding sequences of the Omicron lineages. The mutations identified in this study are highlighted in red. RBD: the receptor binding domain of the spike (S) protein.

2B. Proportion of the different signature mutations in the period of February 22nd to June 6th, 2022. Note that there was a sharp increase of the Omicron variant 2.3.7 from week 4 onwards, and the proportion of this Omicron variant remained high for at least ten weeks. The three signature mutations (S:K97E, N:M322I, ORF1a:L631F) of BA.2.3.7, denoted by filled diamonds, filled triangles, and open circles, are completely overlapped. A steady increase of sequences positive for S:G1251V was noted from week 6 and reached plateau at week 10 (April 26th-May 2nd). In the period of week 11 (May 3rd-May 9th), week 12 (May 10th-May 16th), week 13 (May 17th-May 23rd), week 14 (May 24th-May 30th), and week 15 (May 31st- June 6th), the percentage of ORF1a:T3224A decreased; the percentage of ORF1a:I10917 increased over the same time period.

Fig.2A

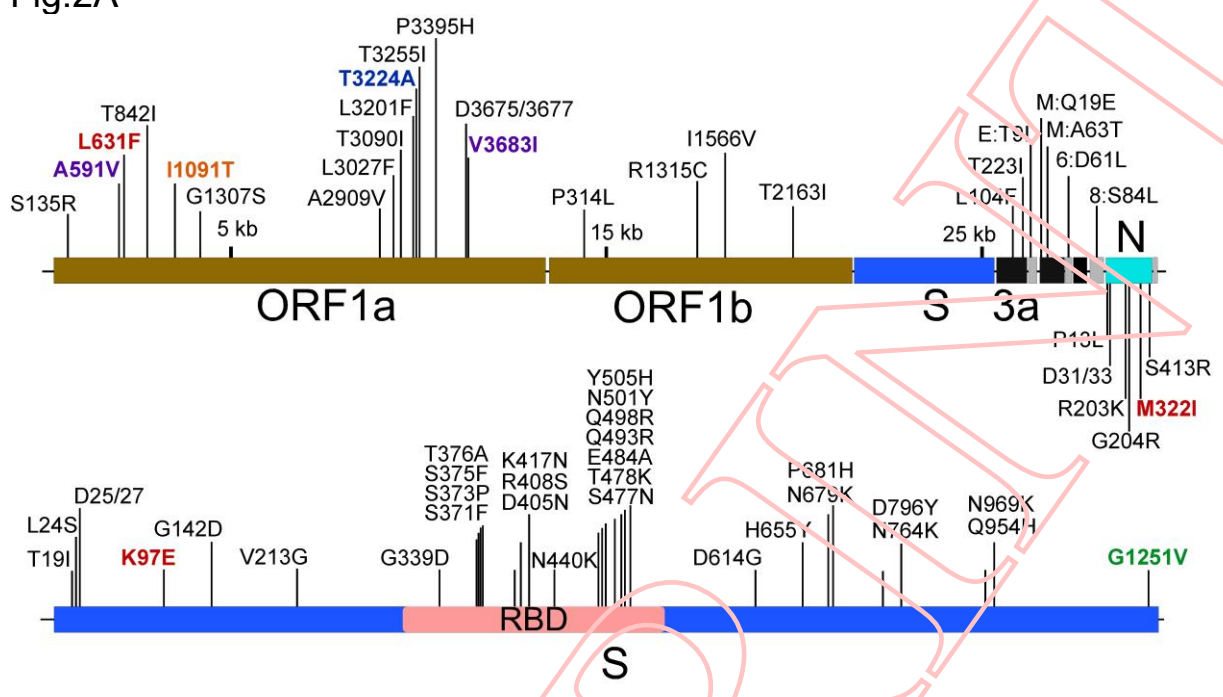

Fig.2B

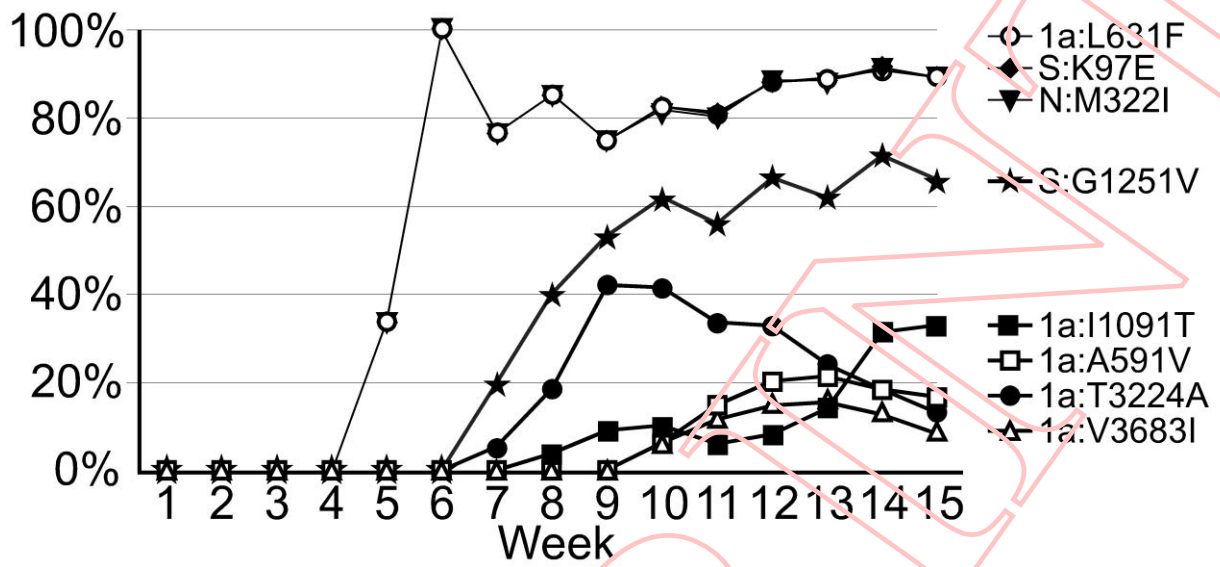

Figure 3. Phylogenetic analysis of the SARS-CoV-2 sequences

3A. We used 1966 sequences from NTU-HCH and 881 sequences from GISAID as a framework for constructing the phylogenetic tree.

3B. We analyzed 1584 BA.2.3.7 sequences submitted to GISAID from the current study together with 228 BA.2.3.7 sequences deposited to GISAID by other groups. The position of signature mutations are indicated; three (S:K97E, N:M322I, ORF1a:L631F) are located at the origin of the B.A.2.3.7 lineages. S:G1251V is mapped at a major branch in the upper trunk of the tree, under which three minor branches can be defined by mutations in ORF1a:T3224A in blue, ORF1a:A591V and ORF1a:V3683I in purple, and ORF1a:I1091T in orange. The origins of the BA.2.3.7 strains and their position in the tree are indicated. An arrow in red denotes the index case collected from Taiwan on March 27th, 2022.

* Using SARS-CoV-2 Wuhan-Hu-1 (MN90847.3) as the reference sequence. Mutations in ORF1b, E, M, 6 and 8 are not shown as they are identical between BA.2, BA.2.3 and BA.2.3.7

† Mutations detected in the Omicron lineages are characterized by the current study
