42 Abstract

43 **Background:** More than half of Chinese patients with hormone receptor positive (HR+) ductal
44 carcinoma in situ (DCIS) are treated with mastectomy, and usually followed by endocrine therapy (ET).
45 Given that long-term ET can cause severe adverse effects it is important to determine the beneficial
46 effect and safety of adjuvant ET after mastectomy on the disease-free survival (DFS) and adverse
47 events in patients with HR+ DCIS.

48 **Methods:** To explore beneficial effect and safety of ET after mastectomy in patients with HR+ DCIS,
49 we performed a multicenter, population-based study. This retrospective study analyzed the DFS and
50 adverse events in 1037 HR+ DCIS Chinese patients with or without post-mastectomy ET from eight
51 Breast Centers between 2006-2016. The median follow-up time was 86 months.

52 **Results:** There were 791 DCIS patients receiving ET (ET group). Those patients were followed-up for
53 a median of 86 months (range, 60-177 months). There were 23 cases with tumor recurrence or distant
54 metastasis. There were similar 5-year DFS rates and DFS between the ET and non-ET groups, even for
55 those with high risk factors. Conversely, 37.04% of patients suffered from adverse events after ET,
56 which were significantly higher than those in the non-ET group.

57 **Conclusion:** ET after mastectomy did not benefit patients with HR+ DCIS for their DFS, rather
58 increased adverse events in those patients. Therefore, ET after mastectomy may not be recommended
59 for patients with HR+ DCIS, even for those with high-risk factors, such as multifocal, microinvasive
60 and higher T stage.

61 **Funding :** This study was supported by grants from Outstanding Scientific Fund of Shengjing
62 Hospital (201803) and Outstanding Young Scholars of Liaoning Province (2019-YQ-10).

63 **Introduction:**

64 Breast cancer screening in adult women has improved its early detection, increasing incidence of ductal
65 carcinoma in situ (DCIS), which currently accounts for >20% of all new breast cancers in USA(Siegel,
66 Miller, Fuchs, & Jemal, 2021) . Breast-conserving surgery (BCS) plus radiotherapy (RT) has been
67 widely used for the control of invasive cancer recurrence(Shah et al., 2016). Recent studies have shown
68 that there is an increase in the percentages of DCIS patients for unilateral and bilateral mastectomy in
69 USA, particularly for young patients(Byun, Wu, Nagar, & Gerber, 2021). There are approximate 30%
70 of DCIS patients receiving mastectomy and potential breast reconstruction, especially for those with
71 widespread, multicentric DCIS in USA(Warnberg et al., 2014; Worni et al., 2015). However, there are
72 near 60% of DCIS patients receiving mastectomy in China, particularly in the economic
73 underdeveloped regions, because they have fear of cancer recurrence (FCR) and subsequent treatment
74 costs.

75 Endocrine therapy (ET) with tamoxifen or aromatase inhibitor (AI) has been recommended for
76 hormone receptor positive (HR+) breast cancer patients after BCS plus RT to reduce the risk of
77 contralateral breast cancer (CBC) and ipsilateral breast tumor recurrence (IBTR) by National
78 Comprehensive Cancer Network (NCCN)(Allred et al., 2012; Forbes et al., 2016; Ganz et al., 2016). It
79 is notable that ET after bilateral mastectomy is not recommended for HR+ DCIS patients, who have a
80 minimal risk for disease recurrence. However, ET still is being used for some HR+ DCIS patients post
81 unilateral mastectomy in Western countries because ET has been thought to reduce the risk of
82 contralateral recurrence of invasive and pure DCIS(Byun et al., 2021). In China, ET has been widely
83 used for HR+ DCIS patients after mastectomy because of FCR although no specific recommendation
84 of ET for them(Mao et al., 2021). Moreover, long-term ET can cause adverse effects, particularly for

85 post-menopausal women. However, there is no report whether ET after unilateral mastectomy can
86 benefit Chinese HR+ DCIS patients for reducing contralateral recurrence of breast cancer and
87 prolonging disease-free survival (DFS) as well as its safety. Accordingly, this retrospective cohort study
88 evaluated the efficacy and safety of ET after mastectomy in the DFS and adverse events of 1037 HR+
89 DCIS patients.

90

91 **Methods**

92 **Subjects**

93 This study was approved by the Institutional Review Board of Shengjing Hospital (approval number:
94 2020PS014K). This retrospective cohort study reviewed and analyzed the DFS and adverse events in
95 1037 HR+ DCIS patients with, or without, ET after mastectomy from December 2006 to August 2016
96 (*Figure 1*). The inclusion criteria included 1) Age > 18; 2) pathological diagnosis of HR+ DCIS
97 regardless of Her-2 status; 3) receiving mastectomy regardless of treatment with ET; 4) complete
98 medical records with regular post-operative follow-up at least for 5 years.

99 **Data collection and statistical analysis**

100 The demographic and clinical data, including age, menopausal status, diagnosis, tumor pathological
101 index, adjuvant treatments (drugs, duration), the ET-related adverse effects, tumor recurrence and
102 survival status were collected. The tumor recurrence was defined as pathologically confirmed breast
103 cancer (DCIS, invasive breast cancer) or metastatic cancers. The DFS was calculated from the
104 diagnosis to the tumor recurrence, or the last follow-up.

105 All patients were stratified, based on ET, and their demographic and clinical data were analyzed by
106 Chi-square, Fisher's exact and Wilcoxon rank sum tests where applicable. Their DFS was estimated

107 using Kaplan-Meier method and analyzed by the Log-rank test. The potential risk of individual factors
108 for the tumor recurrence was analyze by hazard ratios (HR) and 95% confidence intervals (CI). All
109 statistical analyses were performed by SPSS 24.0 software (SPSS, Chicago, USA). Statistical
110 significance was defined when a two-tailed *P*-value of <0.05.

111

112 **Results**

113 **ET after mastectomy does not significantly alter the DFS of HR+ DCIS patients.**

114 A total of 1007 HR+ DCIS patients with mastectomy were selected and their demographic and clinical
115 data, are shown in **Table 1**. According to ET treatment, those patients were stratified in the ET (n=791)
116 and non-ET (n=216) groups. There was no significant difference in any of the demographic and clinical
117 measures tested between these two groups. There were 23 cases (19 vs. 4 between the ET and non-ET
118 groups) with tumor recurrence, leading to 2.40% vs. 1.85% ($p > 0.05$, determined by Fisher exact test)
119 of tumor recurrence rate in the ET and non-ET groups throughout the 12 years post-surgical
120 observation (**Table 2**). There were 4 cases with invasive local recurrence, 3 with contralateral breast
121 cancer, 12 with distant metastasis in the ET group while 4 cases with distant metastases in the non-ET
122 group. Stratification analyses indicated the tumor recurrence rate was not significantly associated with
123 these measures, including high risk factors in this population ($P > 0.05$ for all, **Table 3**).

124 There was no significantly difference in the percentages of patients with a 5-year DFS rate of 98.36%
125 vs. 99.07% between the ET and non-ET groups ($P = 0.44$, **Figure 2A**). Further analysis revealed that
126 there was also no significant difference in the percentages of patients with DFS between these
127 subgroups ($P > 0.05$ for all, **Figure 2B-F**), suggesting that the age, larger tumor size, positive
128 microinvasive, higher tumor grade and Ki67 levels were not associated with increased risk of worse

DFS in this population. Hence, ET after mastectomy did not significantly reduce the tumor recurrence rate and prolong the DFS in HR+ DCIS patient.

The ET-related adverse effects

ET can cause musculoskeletal dysfunction, vasomotor symptoms, gynecological events, cardiovascular events and abnormal liver-function in women, particularly in postmenopausal women. There were 551 patients receiving tamoxifen, 223 with AI and others beginning with tamoxifen and later switching to AI. Analysis of adverse events in both groups revealed that 37.04% of patients in the ET group developed at least one adverse event, including bone fracture or endometrial cancer (n=4 each), while 15.28% of cases with these events in the non-ET group. There were 14.54% of patients with musculoskeletal dysfunctions, such as arthralgia, joint stiffness, osteoporosis or myalgia in the ET group and the percentages of some adverse events tested in the ET group were significantly higher than that in the non-ET group in this population (**Figure 3**). Adverse events between TAM and AI in the ET group are shown in **Table 4**.

Therefore, ET after mastectomy was associated with increased risk for development of different types of adverse effects in patients with HR+ DCIS.

Discussion

Therapeutic strategies for HR+ DCIS, including mastectomy or BCS plus RT, have achieved a similarly high survival rate in patients(Mannu et al., 2020; Narod, Iqbal, Giannakeas, Sopik, & Sun, 2015). Although ET after BCS plus RT is recommended for patients with HR+ DCIS, and benefits for those with positive surgical margin(Allred et al., 2012; Forbes et al., 2016; Ganz et al., 2016; Wapnir et al., 2011), many HR+ DCIS Asian patients chose mastectomy and received ET(Mao et al., 2021; Worni

et al., 2015). In the present study, 78.55 % of HR+ DCIS patients were treated with post-mastectomy ET. More importantly, we found that there was no significant difference in 5-year DFS rate and tumor recurrence rate in HR+ DCIS patients regardless of ET, even in those with high risk factors for tumor recurrence. To the best of our knowledge, this was the first report on the efficacy of ET after mastectomy in the DFS of Chinese HR+DCIS patients and these novel findings clearly indicated that ET after mastectomy did not prolong the DFS of HR+ DCIS patients.

Long-term ET can cause multiple adverse effects, affecting the life-quality of patients. Indeed, 37.04% of patients suffered from adverse events following ET. Quantitative analysis revealed that the percentages of patients with musculoskeletal dysfunction, gynaecological events and abnormal liver-function, but not vasomotor symptoms and cardiovascular events in the ET group were significantly higher than that in the non-ET group of patients. The increased percentages of patients with these clinical symptoms demonstrated that long-term ET caused multiple adverse effects in HR+ DCIS patients after mastectomy. Given that the majority of HR+ DCIS patients chose mastectomy with a long DFS and ET after mastectomy did not prolong their DFS, rather significantly increased ET-related adverse effects in those patients, our findings suggest that ET may be decreased for its dose and duration or completely avoided for HR+ DCIS patients following mastectomy to improve their life-quality.

Several limitations of our study include its retrospective nature and the length of follow-up. To fully evaluate the differences in treatment, longer follow-up and randomized trials are necessary.

Conclusions

ET after mastectomy did not prolong the DFS of HR+ DCIS patients, rather increased adverse effects.

173 Our findings suggest not providing ET for HR+ DCIS patients after mastectomy.
