ABSTRACT (98/100)

The genetic determinants of fractional exhalation of nitric oxide (FeNO), a marker of lung

inflammation, are understudied in Black populations. Alpha globin, which is polymorphic in Black

populations, restricts nitric oxide signaling in arterial endothelial cells. We hypothesized that an

alpha globin gene deletion would be associated with higher FeNO in a cross-sectional study of

643 healthy Black adults. We found that 30% were heterozygous and 4.7% were homozygous

for the deletion. A prespecified additive genetic model found no association with FeNO;

however, a post hoc recessive genetic model suggested that FeNO may be higher among

homozygotes.

INTRODUCTION

Nitric oxide (NO) has numerous biological activities in the lung, serving as a bronchodilator, vasodilator, neurotransmitter, and inflammatory mediator. In asthmatic individuals, the fractional exhalation of nitric oxide (FeNO) is a validated measure of airway inflammation;[1,2] however, little is known about genetic factors influencing FeNO, particularly among Black populations.

Inducible NO synthase (*NOS2*) is the principal source of NO from airway epithelium, and inflammation increases its activity.[3] Genetic variation in the *NOS2* gene has been associated with FeNO levels in healthy individuals, but much of the variation in FeNO remains unexplained.[4] Recently, a new paradigm has emerged whereby NO signaling is restricted by globins expressed in the vascular endothelium that bind directly to NOS.[5] Globins are also expressed in human pseudostratified airway epithelial cells and alveolar epithelial cells, where beta globin colocalizes with endothelial nitric oxide synthase and regulates NO oxidation.[6] This suggests that globins regulate NO signaling not only in the vascular endothelium, but in the airway epithelium as well.

Alpha globin is expressed by the tandem duplicated genes *HBA1* and *HBA2.* A 3.7 kb alpha globin gene (*HBA*) deletion, common in Black Americans, is associated with increased NO signaling in small arteries and protection from kidney disease.[7,8] We hypothesized that healthy Black individuals carrying the alpha globin gene deletion would have increased NO signaling reflected as higher FeNO levels.

METHODS

Black healthy volunteers age 18-40 years were enrolled in a multi-center, cross-sectional cohort from 4 university sites near Durham, North Carolina from 2005 to 2008.[9] The protocol was approved by the Duke University Institutional Review Board (#Pro00004947). Age, sex, race, and ethnicity were self-reported. Only non-Hispanic African American participants were enrolled. Participants were asked to confirm they were healthy (i.e., no chronic illnesses or chronic use of

any medication except oral contraceptives); had no history of asthma, allergic rhinitis, hay fever, or atopic dermatitis; and were nonsmokers. Blood samples were obtained. *HBA* copy number was measured by droplet digital PCR (ddPCR) on genomic DNA. Total serum immunoglobulin-E (IgE) was measured. FeNO was measured in triplicate with a Sievers 280i Nitric Oxide Analyzer (GE Analytical Instruments, Boulder, Colo) according to American Thoracic Society recommendations.[1] A 50 mL/s flow rate was established against resistance to maintain 5 cmH_2O oropharyngeal pressure.[9] Additional exclusion criteria for this analysis were: not consenting to future research and serum cotinine level $\geq$25 ng/mL signifying active tobacco use.

For continuous measures, medians and 25th and 75th percentiles were calculated by *HBA* genotype. Group differences were assessed by Kruskal-Wallis test. Categorical variables were calculated as percentages and differences were assessed by Fisher's exact test. IgE and FeNO were log transformed due to skewness. The association of *HBA* genotype with FeNO was evaluated using multivariable linear regression employing a linear effect of *HBA* gene copy number with adjustment for age, sex, and total serum IgE levels. BMI was previously found not to be associated with FeNO in this cohort and was not included in the model.[9] Two post-hoc sensitivity analyses were performed: one evaluated *HBA* copy number as a categorical variable and one evaluated a recessive mode of inheritance in which the homozygous deletion genotype (-a/-a) was compared against all other genotypes (-a/aa, aa/aa, and aa/aaa).

RESULTS

Of 895 original study participants, 720 consented for future research and had DNA available for genotyping. Sixty-four participants were excluded due to high cotinine levels and 13 were excluded due to indeterminate *HBA* genotype. The remaining 643 participants were 35% male and had a median (25th,75th) age of 20 (19, 22) years, serum IgE level of 58.3 (22, 160) kU/L, and FeNO value of 20 (13, 31) ppb (Table 1).

HBA deletion was common with 30 (4.7%) -a/-a, 197 (30.6%) -a/aa, 405 (63%) aa/aa, and 8 (1.2%) aa/aaa genotypes. Median (25th, 75th) FeNO was 25 (18, 39) ppm in the -a/-a group, 20 (12, 27) ppm in the -a/aa group, 20 (13, 32) ppm in the aa/aa group, and 37 (9, 52) ppm in the aa/aaa group (Kruskal-Wallis p = 0.107; Table 1 and Figure 1). After adjustment for sex, age, and serum IgE, the coefficient for *HBA* copy number with FeNO was -0.005 (95% CI: -0.042, 0.033; p=0.811; Table 2) using the pre-specified additive genetic model. In post hoc sensitivity analyses, the association between the homozygous genotype -a/-a and FeNO was 0.099 (95% CI -0.007, 0.206; p = 0.066) when analyzed as a categorical variable and 0.107 (95% CI 0.003, 0.212; p = 0.045; Table 2) when analyzed using a recessive mode of inheritance.

DISCUSSION

Globins recently emerged as regulators of NO signaling in endothelial and epithelial cell contexts;[5,6] however, the impact of globin gene variation on exhaled NO remains unclear. We characterized a common *HBA* deletion in healthy Black individuals and examined the relationship between *HBA* copy number and FeNO. We found no association between *HBA* genotype and FeNO using a pre-specified additive genetic model; however, a post hoc analysis using a recessive mode of inheritance identified homozygosity for the *HBA* gene deletion to be associated with higher FeNO levels. This latter finding is consistent with the proposed mechanism that alpha globin limits the release of nitric oxide and suggests that lower alpha globin expression allows greater release of NO into airways. More work is needed to determine whether alpha globin binds iNOS in epithelial cells (as it binds eNOS in endothelial cells) and whether this interaction could be targeted to modulate lung inflammation.

Study strengths included the large cohort size, representation of a minority population, high frequency of the *HBA* gene deletion, a well-defined outcome measure, and adjustment for

serum IgE. Limitations included that the significant association was detected in a post hoc analysis, FeNO measurement was performed at a single flow rate that does not distinguish alveolar from bronchial NO sources,[10] and data on the potential confounders of recent upper respiratory tract infection and eosinophilic cationic protein were unavailable.[9]

In conclusion, homozygosity for a common *HBA* gene deletion appears to be associated with higher fractional exhalation of nitric oxide among healthy Black adults.

SOURCES OF FUNDING
