34 **Abstract (294/300 words)**

35 **Background:** Monitoring safety outcomes following COVID-19 vaccination is critical for  
36 understanding vaccine safety especially when used in key populations such as elderly persons  
37 age 65 years and older who can benefit greatly from vaccination. We present new findings from  
38 a nationally representative early warning system that may expand the safety knowledge base to  
39 further public trust and inform decision making on vaccine safety by government agencies,  
40 healthcare providers, interested stakeholders, and the public.

41  
42 **Methods:** We evaluated 14 outcomes of interest following COVID-19 vaccination using the US  
43 Centers for Medicare & Medicaid Services (CMS) data covering 30,712,101 elderly persons.  
44 The CMS data from December 11, 2020 through Jan 15, 2022 included 17,411,342 COVID-19  
45 vaccinees who received a total of 34,639,937 doses. We conducted weekly sequential testing and  
46 generated rate ratios (RR) of observed outcome rates compared to historical (or expected) rates  
47 prior to COVID-19 vaccination.

48  
49 **Findings:** Four outcomes met the threshold for a statistical signal following Pfizer-BioNTech  
50 vaccination including pulmonary embolism (PE; RR=1.54), acute myocardial infarction (AMI;  
51 RR=1.42), disseminated intravascular coagulation (DIC; RR=1.91), and immune  
52 thrombocytopenia (ITP; RR=1.44). After further evaluation, only the RR for PE still met the  
53 statistical threshold for a signal; however, the RRs for AMI, DIC, and ITP no longer did. No  
54 statistical signals were identified following vaccination with either the Moderna or Janssen  
55 vaccines.

56

57 **Interpretation:** This early warning system is the first to identify temporal associations for PE,  
58 AMI, DIC, and ITP following Pfizer-BioNTech vaccination in the elderly. Because an early  
59 warning system does not prove that the vaccines cause these outcomes, more robust  
60 epidemiologic studies with adjustment for confounding factors, including age and nursing home  
61 residency, are underway to further evaluate these signals. FDA strongly believes the potential  
62 benefits of COVID-19 vaccination outweigh the potential risks of COVID-19 infection.

## 63 **Introduction**

64 The US Food and Drug Administration (FDA) is monitoring the safety of three vaccines for  
65 Coronavirus Disease 2019 (COVID-19) currently available in the US. These include the licensed  
66 Pfizer BioNTech vaccine (Comirnaty) for persons 16 years and older and authorized under  
67 emergency use authorization (EUA) for those 12-15 years (BNT162b2), as well as the authorized  
68 Moderna (mRNA-1273), and Janssen (Ad26.COV2.S) vaccines for persons 18 years and older.  
69 Pre-authorization clinical studies provided useful information on the safety of COVID-19  
70 vaccines, but they have limitations such as sample size and follow-up that may be addressed in  
71 post-authorization safety studies in large healthcare databases. Accordingly, FDA and the  
72 Centers for Medicare & Medicaid Services (CMS) are using the Medicare health insurance  
73 database, covering more than 25 million elderly persons aged 65 years and older, to conduct near  
74 real-time safety monitoring of 14 outcomes on a weekly basis following COVID-19 vaccine  
75 administration.

76 The US elderly population, including persons in Long-Term Care Facilities or nursing  
77 homes [1], were disproportionately affected by COVID-19, as they were among the first US  
78 populations to be infected. Because they suffered a higher rate of infection, serious disease, and  
79 severe outcomes including death [2], they were among the first groups recommended by the  
80 Advisory Committee on Immunization Practices to receive the vaccine [3]. Available  
81 information concerning the safety of the vaccine in elderly persons is limited. However, the near  
82 real-time surveillance method used by FDA and CMS continues to expand the available  
83 knowledge base and further advances our understanding of the safety profile of these new  
84 COVID-19 vaccines. The FDA-CMS near real-time active surveillance program complements  
85 other FDA and US Government vaccine safety surveillance systems by rapidly detecting safety  
86 concerns that may not have been voluntarily reported to passive surveillance systems such as

87 Vaccine Adverse Event Reporting System. Routinely used by FDA in safety surveillance for  
88 annual influenza vaccines in the past decade, this method is designed to be sensitive enough to  
89 quickly screen safety signals for further evaluation in robust epidemiologic studies [4, 5]. This  
90 rapid screening method performs hypothesis testing, sequentially, in a prospective manner as the  
91 vaccine data accrue to detect potential safety signals earlier in the course of surveillance, but  
92 signals must be further evaluated in more robust studies with adjustment for confounding.  
93 However, results detected by near real-time surveillance do not establish a causal association  
94 between the outcomes and vaccination because the method has limited adjustments for  
95 confounding.

96 In this report, we summarize the results of weekly sequential testing analyses for 14  
97 outcomes where formal testing was initiated. We also describe how the identified signals were  
98 evaluated and how the epidemiological studies currently underway will provide more robust  
99 adjustment for confounding determine if any are true signals.

100

## 101 **Methods**

### 102 *Data Sources*

103 We used the US Medicare Fee-for-Service (FFS) Parts A (inpatient services) and B (outpatient  
104 care) claims and enrollment data to define inclusion criteria, exposures, outcomes, and patient  
105 characteristics. The number of 65+ beneficiaries with at least 1 day of Medicare FFS enrollment  
106 in the study period is 30,712,101. The Minimum Data Set identified nursing home residency  
107 status.

### 108 *Study Period and Population*

109 The study included Medicare FFS beneficiaries aged 65 years or older who received a COVID-  
110 19 vaccine since December 11, 2020. To be included, individuals needed to be enrolled on the  
111 vaccination date, and continuously enrolled during an outcome-specific pre-vaccination clean  
112 window [6].

### 113 ***Exposure and Follow-Up***

114 Exposure was defined as receipt of a Pfizer-BioNTech, Moderna, or Janssen COVID-19  
115 vaccination, identified using brand and dose-specific Current Procedural Terminology /  
116 Healthcare Common Procedure Coding System codes [7] (Table S1). The primary analysis  
117 included all observed doses by brand. Dose-specific analyses are described in supplemental  
118 materials. Follow-up included all time in the prespecified risk windows; the first-dose risk  
119 window was censored at the time of the second-dose vaccination.

### 120 ***Outcomes***

121 The list of 14 outcomes, pre-vaccination clean windows, and post-vaccination risk windows are  
122 detailed in Table S2. Claims-based outcome algorithms were developed based on literature  
123 review and in consultation with clinical experts [8].

### 124 ***Vaccine Safety Surveillance***

125 Weekly vaccine uptake was monitored by brand. The near real-time surveillance compared the  
126 observed number of each outcome in the COVID-19 vaccinated population to an expected  
127 number based on the background rate of the outcome in a similar COVID-19 unvaccinated  
128 population prior to the pandemic, adjusted for the delay in claims processing and standardized by  
129 nursing home residency status, age, sex, and race. We calculated annual background rates within  
130 the strata of the standardized variables, where possible, during 2017-2019 (pre-COVID-19) and

131 peri-COVID-19 (January 1, 2020–December 10, 2020) [9] (Table S3). If annual rates in the  
132 historical period differed substantially from each other, we selected the minimum rate as a more  
133 conservative approach. Otherwise, the median annual rate was selected.

#### 134 *Statistical Analysis*

135 Poisson Maximized Sequential Probability Ratio Test (PMaxSPRT) was used to detect increased  
136 outcome risk following vaccination compared to a historical baseline for 14 outcomes [10-12]  
137 (Table S3). Weekly sequential testing for each outcome commenced when a minimum of three  
138 cases accrued. One-tailed tests were used, with a null hypothesis that the observed rate was no  
139 greater than the historical comparator beyond a prespecified test margin with an overall alpha of  
140 1%. The test margin was selected for each outcome based on expert guidance to avoid minimal  
141 risk increases that were unlikely to be clinically relevant. The alpha level was selected to address  
142 a large number of tests. A statistical signal occurred if the log likelihood ratio exceeded the  
143 critical value, or a threshold for determining whether the result was likely to occur due to chance.  
144 Additional details are provided in Table S3 and the study protocol [6].

#### 145 *Signal Evaluation*

146 Prespecified signal evaluation analyses were conducted after a statistical signal was observed.  
147 Data quality was checked to rule out database errors or changes in event observation as potential  
148 sources of the signal. Sensitivity analyses evaluated whether the increase in risk was observed  
149 with alternate expected rates in sequential testing – (i) rates from calendar months in the  
150 historical period corresponding to those in the study period to address monthly variations in the  
151 background rates, and (ii) rates among a subset of Medicare beneficiaries with influenza  
152 vaccination in the past year to assess differential healthcare utilization. For pulmonary embolism

153 (PE), additional ad hoc analyses were conducted with (i) the outcome limited to the inpatient  
154 setting and (ii) rates from November 1–December 11, 2020 to address changes in rates in the  
155 peri-COVID period as alternate expected rates.

156 Signal characterization assessed the cases and the potential elevated risk. Analyses  
157 included (i) identifying clusters in the risk window following dose 1 through temporal scans, (ii)  
158 estimating relative risks within demographic strata, (iii) assessing distribution of care settings  
159 and diagnosis codes in observation and historical periods, (iv) comparing patient characteristics  
160 among vaccinated and overall elderly populations, and (v) reviewing patterns of reimbursement  
161 codes by clinicians on a random sample of up to 100 cases per outcome to contextualize the  
162 medical histories of patients.

### 163 *Statistical Software*

164 All analyses were conducted using R 4.0.3 (R Foundation for Statistical Computing, Vienna,  
165 Austria), SAS v. 9.4 (SAS Institute Inc., Cary, NC, United States), and SaTScan v9.6 (Martin  
166 Kulldorff, Boston, MA, United States).

### 167 *Ethical Considerations*

168 This surveillance activity was conducted as part of the FDA public health surveillance mandate.

## 169 **Results**

### 170 *Descriptive Statistics of the COVID-19 Vaccinated Population*

171 From December 11, 2020 through January 15, 2022, 17,088,796 Pfizer-BioNTech, 16,898,376  
172 Moderna, and 634,019 Janssen COVID-19 vaccine doses were found among 30,712,101 eligible  
173 individuals in the study period (34,621,191 total vaccine doses including vaccination days with  
174 multiple products). The population of Pfizer-BioNTech vaccinees had a slightly higher

175 proportion of older individuals (85 years and older), nursing home residents, and individuals  
176 residing in urban areas compared to the general elderly Medicare population (Table 1; Figure 1).  
177 Moderna vaccinees exhibited similar characteristics to the general Medicare population, while  
178 the population receiving the Janssen vaccine was younger and had fewer nursing home residents.

179 **Table 1: Characteristics of Pfizer-BioNTech, Moderna, and Janssen Vaccine Doses Administered among Adults Aged 65 years**  
 180 **and Older in Medicare<sup>a</sup>, Dec 11, 2020 to January 15, 2022**

181 Abbreviations: FFS, Fee-for-Service; SMD, standardized mean difference; AMI, acute myocardial infarction; COPD, chronic obstructive pulmonary disease; COVID-19, coronavirus disease 2019

182 <sup>a</sup> Individuals included in this table were required to have 365 days of continuous enrollment prior to vaccination date in order to accurately capture medical history. Therefore, the total vaccine doses for  
 183 this subpopulation is smaller than the study population of Medicare FFS 65+ study population reported in the Results section.

184 <sup>b</sup> Characteristics of the general Medicare FFS population aged 65 years and older were assessed as of 12/10/2020

185 <sup>c</sup> SMD with values greater than 0.1 are presented in bold text and indicate covariates with larger imbalances between populations

186 **Fig 1. Cumulative COVID-19 Vaccine Doses, by Age and Sex, in Adults Aged 65 Years and**  
 187 **Older in the Medicare Shared Systems Data, by Vaccine Brand, Dec 11, 2020 to January**  
 188 **15, 2022**

189  
 190 Comparing data cuts through April 24, 2021 (Table S6), March 13, 2021 (Table S7) and  
 191 February 27, 2021 (Table S8), the populations differed for those who were vaccinated from mid  
 192 December 2020 to February 2021 versus the later months. Pfizer vaccinees experienced more  
 193 hospitalizations in the prior year and higher proportions of underlying medical conditions (e.g.,  
 194 Charlson comorbidity index > 0), when compared to the overall elderly Medicare, Moderna, or  
 195 Janssen populations.

196 ***PMaxSPRT Sequential Testing Results***

197 All outcomes with primary analyses for PMaxSPRT testing met the prespecified criteria for  
 198 initiation of analyses (Table S3). No statistical signals were identified following vaccination with

199 either the Moderna or Janssen vaccines. AMI (RR=1.42), PE (RR=1.54), disseminated  
200 intravascular coagulation (DIC; RR=1.91), and immune thrombocytopenia (ITP; RR=1.44)  
201 following Pfizer-BioNTech vaccination met the statistical threshold for a signal (Table 2). Dose-  
202 specific results can be seen in Tables S4-5.

203  
204

**Table 2: Summary of Sequential Testing Results in Adults Aged 65 years and Older in the Medicare Shared Systems Database for Any Dose by Vaccine Brand, Dec 11, 2020 to January 15, 2022**

Outcomes, by Vaccine Brand	Vaccine Brand	Observed Person Time (Days)	Number of Doses	Number of Observed Outcomes (as of 01/15/2022) <sup>a</sup>	Relative Risk of Observed vs. Expected (Any Dose; 01/15/2022) <sup>b</sup>	Signal Identified <sup>c</sup>
Acute Myocardial Infarction	Pfizer-BioNTech	402,380,589	15,747,074	13,293	0.97	Yes - 2/27/2021 (RR=1.42)
	Moderna	423,244,936	15,628,229	12,909	0.94	No

	Janssen	19,864,965	576,089	23	1.15	No
Appendicitis	Pfizer-BioNTech	548,982,786	15,880,177	1,180	1.06	No
	Moderna	564,851,514	15,745,889	1,190	1.04	No
	Janssen	19,785,242	576,111	37	0.86	No

<sup>a</sup> \*\* indicates small cell size counts with fewer than 11.

<sup>b</sup> The relative risk incorporates adjustments for observation delay as well as standardization by nursing home residency, sex, age, and race when indicated by in Table 3.

205  
206

207 **Signal Evaluation**

208 None of the prespecified data quality assurance checks, including claims duplication and unusual  
 209 variability in claim accrual, raised data quality concerns (Table S9). Primary findings for signal  
 210 robustness and signal characterization analyses are summarized in Table 3. Adjustment for  
 211 monthly variation in the background rates resulted in statistically non-significant associations for  
 212 AMI, DIC, and ITP following Pfizer-BioNTech vaccination. With background rates from the flu-  
 213 vaccinated population as the historical comparator, DIC and ITP no longer met the signal  
 214 threshold, while signals for AMI (RR=1.41) and PE (RR=1.48) remained. When rates during the  
 215 peri-COVID period were used as the historical comparator, PE and DIC no longer met the signal  
 216 threshold. We conducted an additional ad hoc sensitivity analysis for PE. When PE events were  
 217 restricted to the inpatient setting, the statistical signal remained (RR=2.17).

Type of Evaluation	Evaluation Conducted	Summary of Findings	Interpretation
<b>Signal Robustness</b>	PMaxSPRT with secular trends adjustment	RR no longer statistically significant for AMI, DIC, and ITP. RR reduced but remained statistically significant for PE	Potential confounding for AMI, DIC, and ITP
	PMaxSPRT with expected rates from influenza vaccinated population	RR no longer statistically significant for DIC and ITP. RR remained statistically significant for AMI and PE	Potential confounding for DIC and ITP
	PMaxSPRT with expected rates from peri-COVID-19 time, for PE, DIC, and ITP	RR no longer statistically significant for PE and DIC. RR increased and remained statistically significant for ITP	Potential confounding for PE, DIC
	PMaxSPRT with cases in the inpatient setting only, for PE outcome only	RR increased and remained statistically significant for PE	PE signal robust to inpatient-only definition
<b>Signal Characterization</b>	Summarized covariate distributions of vaccinated individuals compared to the	Pfizer vaccinated individuals had a higher proportion of nursing home residents and older individuals than the general elder	Potential confounding specific to the Pfizer vaccinated population

Type of Evaluation	Evaluation Conducted	Summary of Findings	Interpretation
	general Medicare FFS population aged 65+	population throughout the study period. This was not seen for Moderna or Janssen	
	Reviewed profiles of diagnoses and procedures on claims one year prior to and following case date for 100 sampled cases with clinical experts	Outcome-specific risk factors seen for 41-96% of sampled cases, depending on outcome. Outcome-specific treatments or diagnostics only observed for 18-53% of sampled cases, depending on outcome	Requires further investigation
	Summarized frequency of individual codes and claim settings used to flag outcomes in the historical and observation periods	No differences between periods observed for DIC or ITP.  A higher proportion of Type II AMI codes and non-primary inpatient diagnoses was observed in the observation period compared to the historical period for AMI.  A higher proportion of subsegmental PE codes was observed in the observation period. Additionally, PE case counts in Nov and Dec 2020 were 20–40% higher than in historical period (i.e., 2019)	Requires further investigation
	Summarized frequency of prior COVID-19 diagnosis	Rates of prior COVID-19 diagnoses were higher among Pfizer vaccinated individuals than the general population.  Rates of prior COVID-19 diagnoses were higher among individuals with an AESI than among all vaccinated individuals.	Yes, for all outcomes for which COVID-19 is a risk factor
	Performed temporal scans to identify clusters of cases post-vaccination	No statistically significant cluster for PE, ITP, or DIC. Statistically significant cluster identified from 1–17 days post Pfizer first dose for AMI	No specific narrow clusters of high risk identified for AMI, DIC, PE, or ITP
	Characterized relative risks by patient strata (nursing home residency status, sex, age, race, comorbidities status)	Larger RR in the nursing home residents compared to the non-nursing home residents for AMI (1.53 vs. 1.34), PE (1.66 vs. 1.47), and DIC (2.72 vs. 1.28).  Larger RR in males compared to females for ITP (1.68 vs. 1.28).	For AMI, PE, and DIC elevated risk may be concentrated in the nursing home population

222

223 Clinical subject matter experts reviewed claims-based diagnoses and procedures for  
 224 selected patients from one year prior through one year after the dates of sampled outcome events.  
 225 They found outcome-specific comorbidities were present in 41%, 45%, 95%, and 66% of AMI,  
 226 PE, DIC, and ITP cases, respectively. Additionally, only a single diagnosis without other

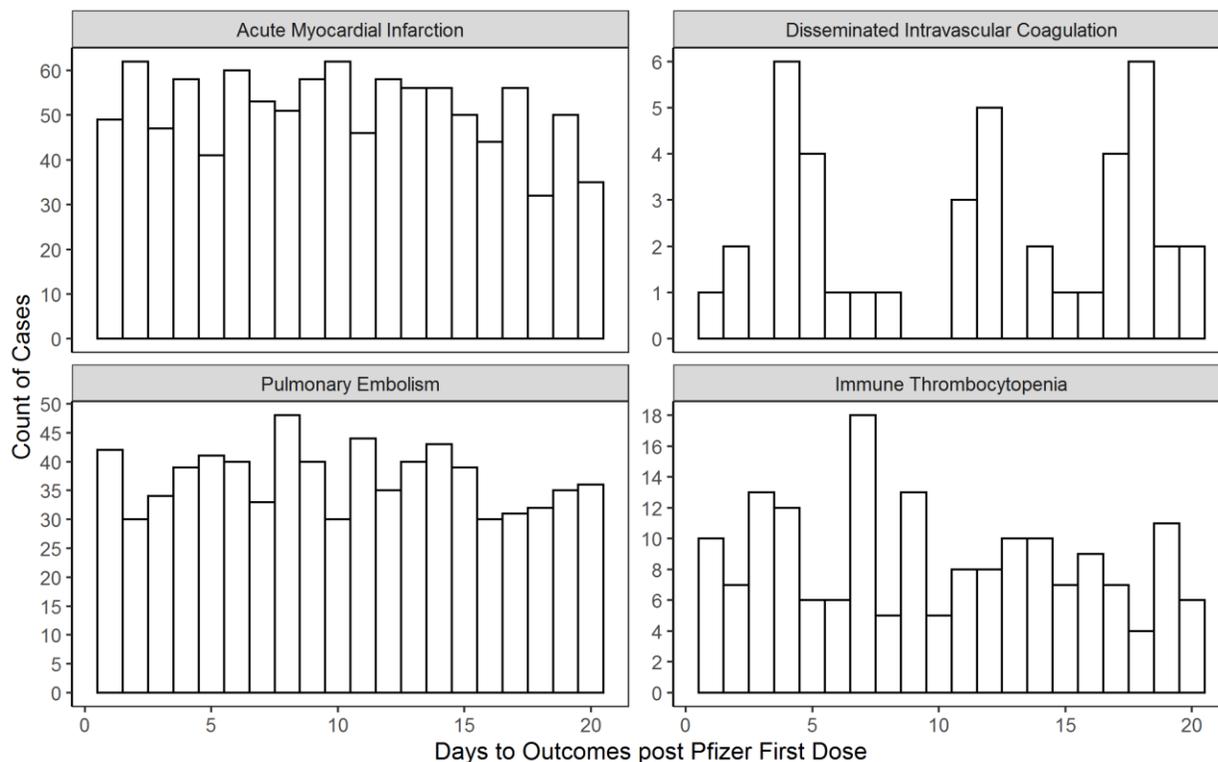

227 mention of the outcome occurred in 26%, 37%, 61%, and 49% of cases for AMI, PE, DIC, and  
228 ITP, respectively. Outcome-specific treatments or diagnostics were observed in 34%, 53%, 40%,  
229 and 18% of AMI, PE, DIC, and ITP cases, respectively.

230 Evaluation of claims-based diagnosis codes showed differences in coding patterns for  
231 AMI and PE between the study period and the historical period used to calculate expected rates  
232 (Table 3). Type II AMI codes, which are indicative of a mismatch between myocardial oxygen  
233 supply and demand (as opposed to acute coronary thrombosis), were more common in outcomes  
234 identified during the study period (46%) than in the historical period (28%). Additionally, for  
235 both AMI and PE outcomes, a higher proportion of inpatient claims-based codes occurred in a  
236 non-primary diagnosis position in the study period. No differences in coding patterns between  
237 the study period and historical period were noted for either ITP or DIC.

238 Finally, temporal scans conducted at the time of signal did not identify any clustering of  
239 cases within the post-vaccination risk window for PE, DIC, or ITP post Pfizer's first dose. A  
240 scan for clusters 1-18 days long identified a statistically significant cluster of 1-17 days for AMI;  
241 however, the observed rate of events in the cluster was only 4% higher than if events had been  
242 evenly distributed in the risk window (Figure 2). Another scan for clusters 1-10 days long that  
243 also accounted for censoring due to end of follow-up did not identify a statistically significant  
244 cluster for AMI (Figure 2).

## 251 Discussion

252 Our early warning safety system is the first to identify four new statistical signals for modestly  
253 elevated risks ( $RR < 2$ ) of four serious outcomes of AMI, PE, DIC, and ITP following Pfizer-  
254 BioNTech vaccination. This FDA and CMS COVID-19 vaccine safety study is one of the largest  
255 studies of elderly persons aged 65 years and above including approximately 34 million doses  
256 administered to more than 17 million Medicare insured persons. Our surveillance monitoring did  
257 not detect statistical signals for the Moderna and Janssen vaccines for any of the 14 monitored  
258 outcomes.

259 The statistical signals of four serious outcomes are not necessarily causal and may be due  
260 to factors potentially unrelated to vaccination. Additional analyses indicated that the potential

261 association was less than twice the historical rates and may be associated with factors not  
262 accounted for in the near real-time surveillance methods. For example, the elderly Medicare  
263 population that received the Pfizer-BioNTech vaccine differed from other elderly COVID-19  
264 vaccinated populations, including a preponderance of nursing home residents and populations  
265 with a higher comorbidity burden. These demographic and medical differences were not fully  
266 accounted for, since expected rates were only standardized to a subset of characteristics – age,  
267 sex, race, and nursing home residency status. Further, the AMI, DIC, and ITP signals were not  
268 robust when additional baseline rates were evaluated, while the PE signal might be explained by  
269 differences in rates between the pre-COVID-19 and peri-COVID-19 periods. In addition, the  
270 clinical assessment of patterns of reimbursement codes indicated that a substantial fraction had  
271 pre-existing outcome-specific comorbidities and risk factors, and that some outcomes may be  
272 due to follow-up care to an existing condition preceding the vaccination.

273         Our study has several strengths. This is the largest study of a population of more than 25  
274 million elderly persons who are vulnerable to COVID-19 infections and complications-  
275 including residents of long-term care facilities. By using the large Medicare nationwide database  
276 with longitudinal linkage of vaccination, health services, and demographic information for  
277 millions of elderly persons, we can detect even small increases in the relative risk of rare  
278 outcomes for multiple vaccines that may not be captured in pre-authorization clinical trials. In  
279 addition, this near real-time surveillance benefits from the experience and knowledge obtained  
280 during more than a dozen years of successful collaboration between FDA and CMS conducting  
281 vaccine safety analyses using the Medicare database [13], including near real-time surveillance  
282 analyses for Guillain-Barré syndrome after influenza vaccination [14-16]. Furthermore, the  
283 weekly data updates and analyses allow for signal detection across 14 outcomes using near-real

284 time monitoring. This further expands our knowledge of COVID-19 vaccine safety for informing  
285 timely regulatory action, if warranted as well as decision-making by healthcare providers,  
286 patients and the general public

287 We acknowledge our analysis has limitations. The near real-time analysis did not adjust  
288 for underlying risk factors such as comorbidities among recipients in the early vaccination  
289 campaign leading to falsely positive or negative signals. Furthermore, the early warning system  
290 may falsely identify a signal (false positive) or signals because of the high number of statistical  
291 tests performed or possible misspecification of parameters. Conversely, true safety signals (false  
292 negatives) may be missed due to misspecified parameters in the analyses. Diagnosis billing codes  
293 in claims data may underestimate or overestimate certain clinical conditions because of  
294 reimbursement priorities. We also note that results of this near real-time surveillance in elderly  
295 persons may not be generalizable to those younger than 65 years and adults who are uninsured or  
296 received only commercial health insurance. To address several of these limitations we are  
297 conducting further epidemiological studies along with medical record review to adjudicate  
298 outcomes identified by claims-based definitions.

299 In conclusion, we demonstrate that this FDA-CMS early warning safety system is  
300 working to rapidly identify potential new and important safety concerns following COVID-19  
301 vaccination for consideration and to support potential decision-making by regulatory and public  
302 health authorities, healthcare professionals and the general public. Our new findings of statistical  
303 signals for four important outcomes for the Pfizer-BioNTech vaccine should be interpreted  
304 cautiously because the early warning system does not prove that vaccines cause the safety  
305 outcomes. FDA strongly believes the potential benefits of COVID-19 vaccination outweigh the  
306 potential risks of COVID-19 infection. Per FDA communication of these findings, FDA is

307 currently not taking any regulatory actions based on these signal detection activities because  
308 these signals are still under investigation and require more robust study. The FDA active  
309 surveillance systems, including the CMS partnership, are a major part of a larger US federal  
310 surveillance effort to increase knowledge of COVID-19 vaccine safety to support decision-  
311 making that further protects public health during the pandemic.
