15 ABSTRACT

16 Background

17 In mid-2021, widespread availability of COVID-19 vaccines with demonstrated impacts on transmission
18 promised relief from the strict public health and social measures (PHSMs) imposed in many countries to
19 limit spread and burden. We were asked to define vaccine coverage thresholds for transition through the
20 stages of Australia’s ‘National Plan’ to easing restrictions and reopening international borders.

21 Methods

22 Using available evidence of vaccine effectiveness against the then-circulating Delta variant, we used a
23 mathematical model to determine vaccine coverage targets. The absence of any COVID-19 infections
24 in many sub-national jurisdictions in Australia posed particular methodological challenges for modelling
25 in this setting. We used a novel metric called Transmission Potential (TP) as a proxy measure of the
26 population-level effective reproduction number. We estimated TP of the Delta variant under a range of
27 PHSMs, test-trace-isolate-quarantine (TTIQ) efficiencies, vaccination coverage thresholds, and age-based
28 vaccine allocation strategies.

29 Findings

30 We found that high coverage of vaccination across all age groups ($\geq 70\%$) combined with ongoing
31 TTIQ and minimal PHSMs was sufficient to avoid strict lockdowns. At lesser coverage ($\leq 60\%$) rapid
32 case escalation risked overwhelming of the health sector and would prompt a need to reimpose strict
33 restrictions, with substantive economic impacts in order to achieve the goals of the National Plan.
34 Maintaining low case numbers was the most beneficial strategy for health and the economy, and at higher
35 coverage levels ($\geq 80\%$) further easing of restrictions was deemed possible.

36 Interpretation

37 These results reinforced recommendations from other modelling groups that some level of PHSMs should
38 be continued to minimise the burden of the Delta variant following achievement of high population vaccine
39 coverage. They directly informed easing of COVID-19 restrictions in Australia.

45 economic modelling

47 INTRODUCTION

48 Since early 2020, rapid dissemination of SARS-CoV-2 and subsequent emergence of variants have resulted
49 in multiple rapidly escalating waves of infection with devastating impacts on health, society and the
50 economy [1]. In contrast with the rest of the world, many island nations in the Western Pacific Region
51 remained relatively COVID free through the first two years of the pandemic as a result of strong border
52 controls to prevent importation, and reactive imposition of social restrictions to constrain community
53 transmission (e.g. [2, 3]). These measures enabled enviable social freedoms and ongoing economic
54 activity, but such disconnection from the international community was not a sustainable strategy over the
55 longer term [4].

56 Global concerted efforts to accelerate development and licensure of safe and effective vaccines raised
57 hopes that wide scale population immunisation would enable a return to ‘life as normal’ in high burden
58 settings, given demonstrated impacts on infection acquisition and onward spread [5, 6, 7]. For countries
59 that had pursued a low or zero-COVID strategy, ‘living with COVID’ seemed an achievable goal if
60 vaccines could constrain transmission and mitigate disease outcomes sufficiently to avoid overwhelming
61 the health system following SARS-CoV-2 importation, while maintaining near normal societal functioning
62 [8, 9]. However, anticipating the likely impacts of introducing COVID-19 into an environment without
63 established SARS-CoV-2 transmission is difficult [10].

64 To address this challenge, we developed a Transmission Potential (TP) [10] metric to quantify the
65 likely spread of COVID in populations based on behavioural, social mixing data and available case
66 data. TP is an estimate of the average population-level trend in the effective reproduction number (R_{eff})
67 and is driven by factors that influence transmission from local cases. Relevant considerations include
68 the effectiveness of test-trace-isolate-quarantine (TTIQ) case and contact management [11], as well as
69 changes in personal distancing behaviour and mandated constraints on mixing group sizes, collectively
70 termed public health and social measures (PHSMs) [10]. Demonstrated reductions in TP achieved by
71 these interventions can be incorporated into future scenario projections, along with anticipated impacts
72 of vaccination on transmission [REF vaccination efficacy/TP paper]. International evidence of vaccine
73 effectiveness against acquisition and onward spread of the Delta variant was used to estimate the likely
74 overlaid impact of differing levels of vaccine coverage (by age cohort) on population wide TP.

75 This approach was used in mid-2021 to help inform Australia’s National Plan to transition Australia’s
76 National COVID-19 response[12], by determining target vaccination thresholds for moving between its
77 four phases (table 1), including any ongoing requirement for public health responses and social measures.
78 These methods formed the basis for further collaborative work with the Australian Government Treasury
79 to determine likely economic implications of reopening at alternative thresholds based on the level of
80 adjunct PHSMs needed [13], and constituted part of a broader suite of modelling advice to the Australian
81 Government to inform management of the pandemic and a shift away from strict lockdown measures
82 [14, 15, 16]. From the outset, it was anticipated that reopening targets in populations naïve to COVID-19
83 would be higher than for those with a history of prior circulation resulting in some degree of established
84 immunity to the virus.

85 METHODS

86 Transmission Potential

87 Transmission potential (TP) is a measure of the average potential for a virus to spread at the population
88 level [10]. It can be considered as an estimate of the reproduction number, if transmission were widespread
89 (and therefore not concentrated in one demographic group with non-representative transmission rates). The
90 base model consists of three sub-models involving time to detection and isolation of cases, and two types
91 of physical distancing behaviour: we differentiate “macro-distancing” as the reduction in the average rate
92 of non-household contacts (e.g. in response to lockdown-type restrictions), while “micro-distancing” is the
93 reduction in transmission probability per non-household contact (e.g. adherence to social-distancing and
94 hygiene advice or legislation; [10]). Transmission potential will vary among communities by differential
95 average household size and age structures, and can be modulated by changes to behaviour through public
96 health and social measures, time to detection and isolation of cases, and immunity through infection and
97 vaccination. A full description of this model can be found in Golding and colleagues [10]. Whilst an

Table 1. Phases of the “National Plan to transition Australia’s National COVID-19 Response”[12]. Our modelling analysis focuses on the transition from ‘phase A’ in which strong suppression and no community transmission is the goal, to ‘phase B’ where vaccine coverage is high and SARS-CoV-2 infection is allowed to establish in the population. Scenarios therefore examine the epidemic dynamics and clinical consequences of infections following seeding of an epidemic at different vaccination coverage thresholds achieved through alternative age prioritisation strategies.

| Phase | Description | Activities |
|-------|------------------------------|--|
| A | Vaccinate, Prepare and Pilot | Continue to strongly suppress the virus for the purpose of minimising community transmission |
| B | Vaccination Transition | Seek to minimise serious illness, hospitalisation and fatality as a result of COVID-19 |
| C | Vaccination Consolidation | As above |
| D | Post-Vaccination | Manage COVID-19 consistent with public health management of other infectious diseases |

98 estimate of transmission potential under a given scenario of R_0 , behaviour, and health system performance
99 can never be a perfect predictor of a reproduction number due to epidemic stochasticity and unaccounted
100 sources of variation, it is a measure that enables prediction of the likely ability to control spread in the
101 event of widespread transmission, and has been used as a systematically reported situational assessment
102 metric in Australia since 2020 [17, 18, 19].

103 **Test, Trace, Isolate, and Quarantine**

104 Test-trace-isolate-quarantine (TTIQ) strategies are key non-pharmaceutical interventions used globally
105 to manage infectious disease outbreaks [20, 21] including frequently during the COVID-19 pandemic
106 [22, 23]. TTIQ operates through isolating cases identified by testing, and tracing and pre-emptive
107 quarantining of their close contacts to prevent further onward transmission. We adapted our TP model
108 to include an explicit effect of reducing the time to case isolation achievable through intensive contact
109 tracing, in addition to the time to case detection effect already included [11]. The empirical distribution of
110 times from symptom onset to case isolation under an ‘optimal’ TTIQ capacity (i.e. with a health system
111 that had enough capacity to rapidly contact trace all cases) was estimated using a limited time series of
112 case data from the state of New South Wales between July 2020 and January 2021, for which dates of
113 isolation were known with a high level of data completeness. This distribution was then calibrated to
114 estimate the distribution of times to isolation in other times and states by assuming improvements in TTIQ
115 are proportional to improvements in times to detection. We characterised a second level of ‘partially’
116 efficacious TTIQ based on observations from the state of Victoria on 4 August 2020. This date was the
117 then-peak of daily locally-acquired COVID-19 cases in Australia representing a contact-tracing system
118 under resource constraints. These data were used to estimate the effect of ‘partial’ TTIQ on transmission
119 potential to estimate a baseline TP under community transmission. These estimates of ‘optimal’ and
120 ‘partial’ TTIQ correspond to a 54% and 42% reduction in transmission respectively; the full details of this
121 estimation are found in [11].

122 **Public Health and Social Measures**

123 In the presence of ongoing viral transmission, it is necessary to keep the rate of virus reproduction, R_{eff} ,
124 below or close to 1, as any extended periods where $R_{eff} > 1$ can quickly lead to significant numbers of
125 cases, causing stressors on health systems. So maintenance of R_{eff} near or below 1 is needed both to
126 contain community transmission in the suppression phase, and to prevent cases from exceeding health
127 sector capacity after re-opening. Regulated or advised risk reduction behaviours and constraints on social
128 mixing described collectively as public health and social measures (PHSMs) are the levers that may be
129 employed to manage R_{eff} in response to incursions and outbreaks. Behaviours change over time either
130 spontaneously because of heightened concern or complacency, or in response to mandated public health
131 orders invoking various elements of PHSMs.

132 Here we investigated what level of PHSMs would be required to bring TP to near or below 1 under
133 different scenarios of vaccination coverage. In collaboration with the Australian Government Treasury
134 we defined four ‘bundles’ of PHSM restrictions: baseline, low, medium and high. Each bundle is drawn

135 from a specific time and place in Australia’s pandemic experience, thereby capturing both real-world
136 behavioural responses and the proportional reduction in TP achievable by PHSMs in this context. They
137 therefore represent differing degrees of social constraints for which the impact on TP and economic
138 activity could be defined from historical observations.

139 Full descriptions of measures included in these bundles are in table S1. These bundles are intended to
140 reflect the plausible behavioural consequences of different levels of stringency of PHSM. As such, the
141 ‘Baseline PHSM’ bundle reflects behaviours during a period with minimal restrictions, and a population
142 aware of the risk of COVID-19 (as opposed to behaviour prior to the pandemic). The other bundles reflect
143 the behavioural effects of increasing levels of stringency. We emphasise that the TPs associated with these
144 PHSM bundles reflect state wide population behaviours (numbers of household contacts and adherence to
145 hygiene advice) estimated at these times. TPs are observed to differ substantially over time and between
146 states, even within similar restrictions [10, 18]. These periods are therefore intended to reflect achievable
147 levels of reduction in TP via PHSMs, rather than inference about the particular impacts of these sets of
148 restrictions.

Table 2. Description of measures implemented under different ‘bundles’ of public health and social measures (PHSMs). Each bundle relates to a specific time and place in Australia’s pandemic experience up to mid-2021 — thereby capturing behavioural responses and the proportional reduction in TP achievable by PHSMs in the Australian context. The proportional reductions in TP observed at each time and place can therefore be related to similar reductions achieved via other combinations of PHSMs (not limited to the “bundles” in place during the reference period). Similarly, the imposition of any given combination of PHSMs at different times and places may result in variable population responses and thus reductions in TP. More detailed descriptions of the bundles can be found in S1

| PHSM bundle | Description |
|-------------|--|
| Baseline | Minimal density/capacity restrictions and no major outbreaks as in NSW March 2021 |
| Low | More stringent capacity restrictions compared to baseline (<i>e.g.</i> , hospitality venues limited to 10 customers per booking), as in NSW 23 August 2020 |
| Medium | Stringent capacity restrictions, group size limits (<i>e.g.</i> , fewer than five people outdoors), stay-at-home orders (except work, study, essential purposes), as in NSW 1 July 2021 |
| High | No household visitors, curfew, stay-at-home orders (except essential purposes and permitted work), schools closed (remote learning only), as in VIC 23 August 2020 |

149 **Age-structured Vaccination Impact on Transmission**

150 In keeping with WHO guidance [24] and many other countries, Australia’s immunisation program initially
151 prioritised health- and aged-care workers, elderly populations and those at increased risk of transmission
152 and/or severe outcomes [25]. When defining overall target coverage thresholds for the eligible population,
153 an important goal was to consider the distribution of doses received across age categories. While older
154 individuals are more likely to experience severe disease outcomes, young and working adults are expected
155 to make a greater contribution to transmission at the population level. So to explore the effect of age-
156 structured vaccination on transmission, we explored four allocation strategies: oldest first, 40+ years first,
157 all adults, and transmission reducing, described in table 3 (the specific percentages of each age-group
158 vaccinated in these strategies can be found in [16]). These strategies were motivated by being the strategy
159 in place at the time (oldest first), and a series of what were considered the only other practical options. The
160 strategies followed the Australian Therapeutic Goods Administration [26, 27] and Australian Technical
161 Advisory Group on Immunisation [28] advice on which vaccines were administered to which age-groups
162 and the dosing interval between first and second doses 4. We also assume a two week delay from
163 administration until a vaccine takes full effect 4.

164 We estimated the percentage reduction in TP that could be expected under different vaccination
165 coverages and distributions by age, vaccine type, and the number of doses received, via static analysis of
166 an age-based transmission matrix, S2, [29]. Age-specific susceptibility and transmissibility estimates [30]
167 are used and transmission rates have been calibrated to a baseline population-wide TP of 3.6. TP will be

168 influenced by spontaneous and imposed changes in physical distancing behaviours, the number of social
169 contacts on average between individuals and the timeliness of TTIQ measures. We use a baseline TP of
170 3.6 for the Delta variant based on averaged observations from the state of New South Wales in March
171 2021, a period with minimal social restrictions and no major outbreaks.

172 For each vaccination scenario, the reduction in transmission by age-group was calculated from the
173 average vaccination efficacy against transmission (accounting for the fractions of each vaccine type and
174 number of doses in that age-group) and the age-group coverage. Proportional reductions in transmission
175 rates for each age combination were then applied to the original ‘unvaccinated’ transmission matrix to
176 construct a ‘vaccinated’ matrix. The dominant eigenvalue, representing the population-wide reproduction
177 number was compared between these pairs of matrices to compute a percentage reduction in TP due to
178 immunisation.

179 To explore and visualise the effect of different strategies on TP reduction among age categories, we
180 also calculated an age-group specific TP prior to and after vaccination under a given scenario. These
181 ‘by-age’ contributions are calculated for a given homogeneous age-group (whereas other TP calculations
182 use all age groups concurrently S2). Because these age-specific TP calculations exclude interactions with
183 other age-groups, they are not equivalent to the partial contribution of that age group to the overall TP.

Table 3. Vaccine allocation strategies and allocation sequence by age-group. The specific modelled percentages of each age-group vaccinated in these strategies can be found in [16].

| Strategy | Allocation sequence |
|-----------------------|---|
| Oldest first | Vaccinations are prioritised from oldest to youngest. Specifically, prioritization occurs in the following order: 80+, 70-79, 60-69, 50-59, 40-49, 30-39, 20-29, 16-19 |
| 40+ years first | Vaccinations are prioritised from 40+ upwards, then 16+. Specifically, prioritization occurs in the following order: 40-49, 50-59, 60-69, 70-79, 80+, 16-19, 20-29, 30-39 |
| All adults | Vaccinations are not prioritised in any particular order by age |
| Transmission reducing | As for national program, under which all individuals 40+ were eligible as at the 12 th of July 2021. Within the simulation time-frame, the 30-39 years cohort becomes eligible from the 30 th of August 2021, and 16-29 years on the 11 th of October. |

184 Time in Lockdown

185 During outbreak suppression in Australia, early and stringent lockdowns were used to bring TP below 1
186 for the purposes of driving even a handful of local cases from an outbreak to zero, in the context of an
187 optimal TTIQ response. The goal of transitioning to phase B 1 was to minimise the requirement for such
188 stringent PHSMs, restricting their use to meet the explicit objective of prevention of overwhelming the
189 health sector in the face of escalating case loads.

190 Ongoing application of some degree of social measures through this phase to support vaccine impacts
191 reduces the likelihood for high restrictions and preserves TTIQ effectiveness by keeping case numbers
192 low. TP estimates with and without stringent PHSM can be used to calculate the approximate proportion
193 of time those stringent measures would need to be in place to prevent exceedance of health sector capacity
194 over a defined time frame. This simple static analysis can indicate the plausible societal and economic
195 impacts of the PHSM required to constrain transmission under each scenario and coverage.

196 Where a vaccination scenario leads to either a $TP_1 > 1$ with one PHSM bundle and $TP_2 < 1$ with
197 a more stringent bundle, the long-term average TP can be maintained at 1, i.e. with daily case counts
198 neither growing nor shrinking over the long term, by alternating between the two PHSM bundle states.

Table 4. Vaccine eligibility, dosing intervals, and assumed delay to efficacy.

| Vaccine | Eligible population | Dosing interval | Delay to full efficacy |
|---------------------------------|---------------------|-----------------|------------------------|
| Vaxzevria (ChAdOx1-S) (AZ) [27] | 60+ years [28] | 12 weeks | 2 weeks |
| Comirnaty (BNT162b2) (Pf) [26] | 16+ years | 3 weeks | 2 weeks |

199 Whilst the first PHSM bundle is in place cases will grow, and whilst the more stringent bundle is in place
200 cases will shrink, leading to an oscillation of case counts around some average level S_1 . This fraction of
201 time under more stringent PHSMs is independent of the sequence or duration of the periods under more
202 stringent restrictions; a strategy of rapid switching on and off of restrictions, or one of alternating long
203 periods with or without restrictions would both lead to long-term maintenance of $TP = 1$, provided the
204 fraction of time in each condition is the same S_1 .

205 Switching between more and less stringent PHSMs reflects a strategy that might be used to keep cases
206 below a health sector capacity limit in the event that there is long-term community transmission. With the
207 the necessary simplifying assumption that vaccination coverage is static, where one PHSM bundle leads
208 to growing cases numbers ($TP_1 > 1$), and a second bundle leads to contracting case numbers ($TP_2 < 1$),
209 we can calculate the fraction of time necessary under each bundle of PHSMs S_1 . However this strategy
210 will not always be either necessary or possible. When cases under both bundles lead to declining case
211 numbers (i.e. $TP_1 < 1$ and $TP_2 < 1$), the fraction is zero as the more stringent PHSM bundle is not needed.
212 Alternatively, where even the more stringent PHSMs still lead to growing daily case numbers ($TP_2 > 1$)
213 no fraction exists, because even the more stringent PHSM bundle could not control transmission.

214 **Costs of PHSMs**

215 The Australian Government Treasury estimated the direct economic costs of alternative COVID-19
216 management scenarios explored in this analysis. Estimates included the expected average weekly costs
217 of activity restrictions and lockdowns for each of the bundled levels of restrictions, multiplied by their
218 duration of application over the specified timeframe. These figures were derived by analysing the impact
219 on hours worked across the economy during lockdown periods in 2020, compared with the pre-COVID
220 baseline. They did not include indirect confidence effects, labour market impacts, social, fiscal or health
221 economic costs. For all scenarios it was assumed that case numbers would be constrained by social
222 measures to avoid overwhelming the health system. An objective of maintaining low case numbers in this
223 way was to avoid the significant behavioural changes and related economic impacts that were observed
224 in other country settings where severe and widespread outbreaks occurred in the absence of mixing
225 restrictions. [13].

226 **Data Analysis**

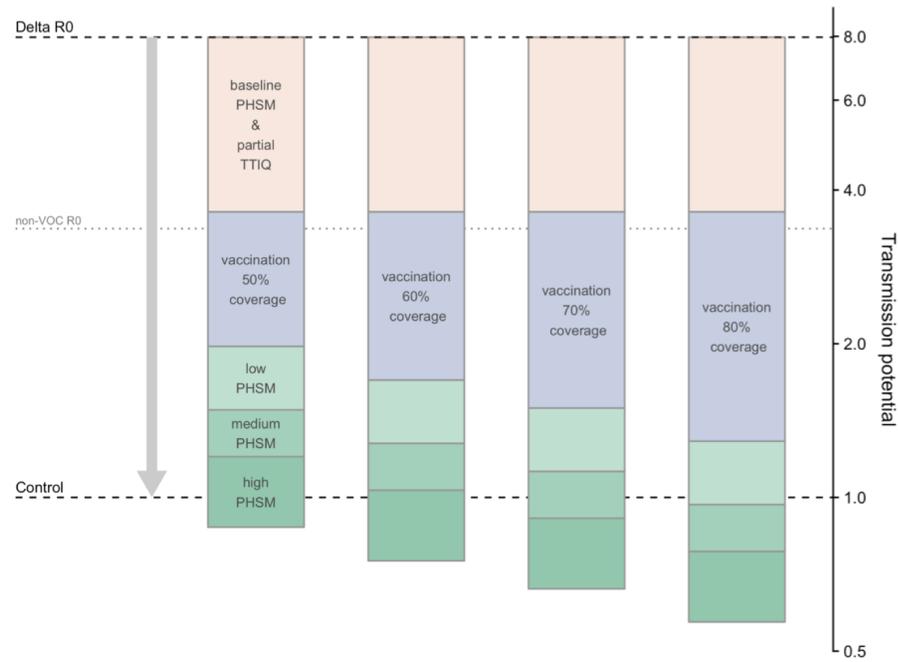

227 All data analyses for this work were carried out in R [31]. R code to reproduce these analyses are available
228 at <https://github.com/aus-covid-modelling/NationalCabinetModelling>. This
229 code uses outputs from regular situational assessment work [19, 18] that are conducted using data provided
230 under confidential agreement from the Australian Commonwealth Government (see also statement in
231 Ethics), and that the authors are not authorised to make available. Code to create figures 3 and S1 can be
232 found in [32].

233 **RESULTS**

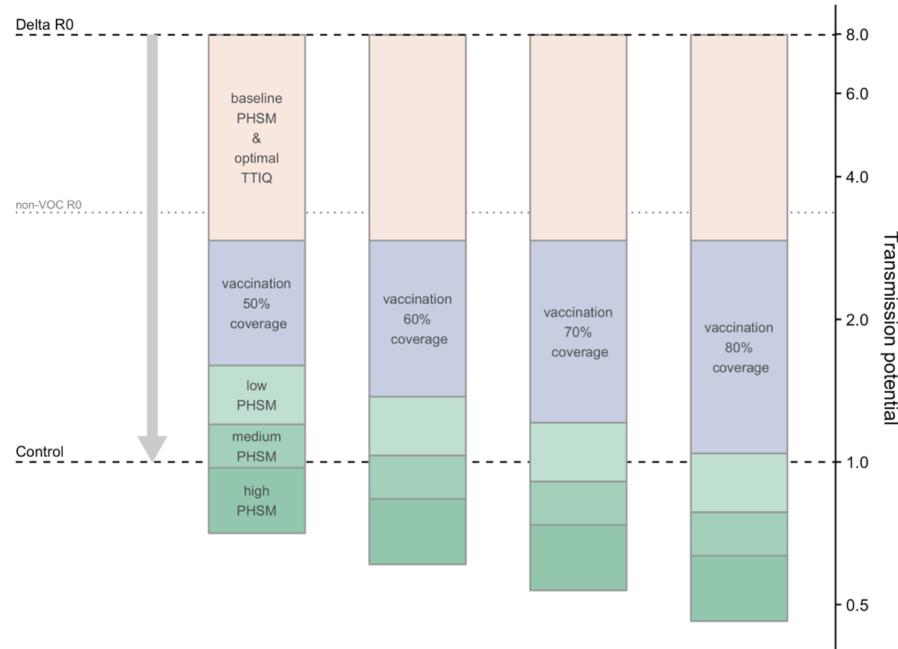

234 From an R_0 of 8 for the Delta variant, with baseline PHSMs and partial TTIQ in place TP is reduced
235 to 3.6, which serves as a baseline to which other interventions are added 1. The effects of vaccination
236 and more stringent PHSMs on TP are mathematically multiplicative, so the results displayed in figure 1
237 use a logarithmic y-axis in order to easily see the relative magnitude of each intervention. The results
238 demonstrate that as vaccination coverage increases, less stringent PHSMs are required to bring TP
239 below 1 and thus control epidemic activity (figure 1). Maintaining a rapid and highly effective TTIQ
240 response capacity is critical for ongoing epidemic control. Should TTIQ responses become only partially
241 effective due to high caseloads, high PHSM would be needed to curb transmission at the 50% and
242 60% coverage thresholds, whilst low PHSMs may be sufficient for control at 80% coverage (figure
243 1). More optimistically, the combination of 70% vaccine coverage and ongoing low PHSMs would
244 likely be sufficient for control, if optimal TTIQ can be maintained (figure 1). Note that compliance with
245 imposed measures will vary their effectiveness between populations and time-points. This uncertainty is
246 conceptually represented by the upper and lower bounds of each 'box' for each set of restrictions in figure
247 1.

248 The choice of age-structured vaccine allocation strategy has a slight effect on Transmission Potential,
249 though this varies with level of vaccine coverage (table 5). The contribution varies considerably by
250 age-group due to differential mixing rates (figure 2, and figures S3, S4, and S5), and while a transmission

(a) Partial TTIQ.

(b) Optimal TTIQ.

Figure 1. Combined effects of vaccination and PHSM scenarios on COVID-19 transmission potential under the ‘Transmission reducing’ vaccination scenario assuming only partial (a) or optimal (b) TTIQ effectiveness, due to high caseloads. (NB the logarithmic scale of the y-axis enables comparison of the multiplicative effect sizes of these measures without depending on the order of in which they are plotted.)

It is made available under a [CC-BY 4.0 International license](https://creativecommons.org/licenses/by/4.0/).

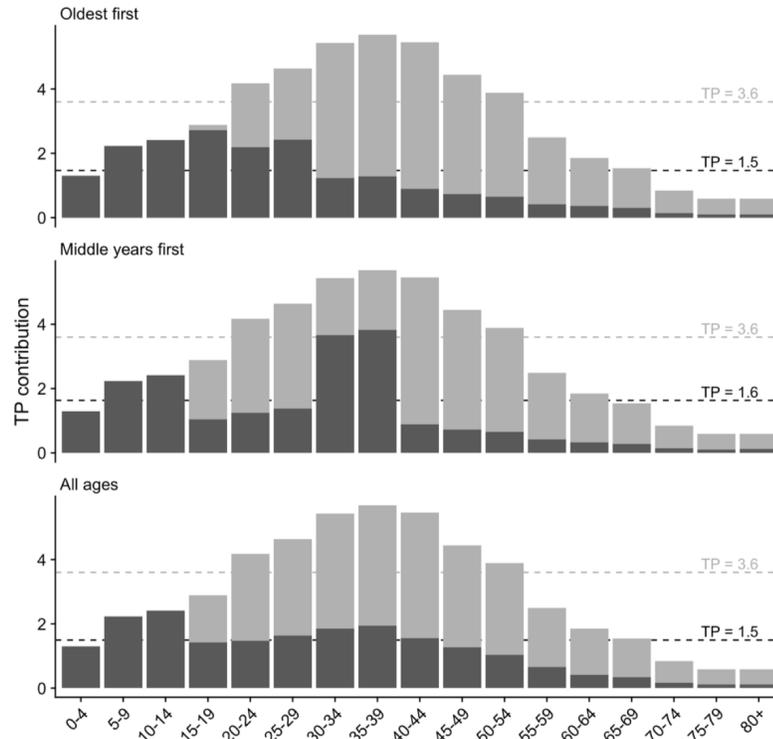

Figure 2. Impact of the four different vaccine allocation strategies on TP by age category, resulting in the overall TP achieved by 70% age eligible population coverage. Dark grey represents TP contribution after vaccination, and light grey in the absence of vaccination. Other coverage levels (50, 60 and 80% are in figures S2a-c). Dashed lines correspond to whole population differences in TP with age-group interactions included.)

251 reducing allocation strategy tends to best reduce TP as intended the effect is slight, and the advantage
 252 depends on the overall coverage level of vaccination. Vaccinating the 40+ years first tended to perform
 253 worst at lower levels of coverage, requiring the largest proportion of time under strict PHSMs, however
 254 this became unimportant at higher levels of vaccination.

255 Tables 6 and 7 compare the proportion of time that would need to be spent with high PHSM on top of
 256 ongoing light restrictions to maintain case counts at some level, by vaccine coverage and allocation
 257 strategy. We assume periodic switching between low PHSM and high PHSM over a long period with
 258 the same vaccination coverage. With long-term coverage held at 50%, 60%, or 70%, high PHSM would
 259 be needed for significant fractions of time (18-89%) if caseloads escalate, leading to ‘partial’ TTIQ
 260 effectiveness. For the ‘optimal’ TTIQ scenario and an achieved adult population coverage of 70%, high
 261 PHSM would be needed rarely if at all.

262 Figure 3 represents the proportion of time spent under each of the restriction stringency settings

Table 5. Scaled values of Delta variant transmission potential (TP) for 50%, 60%, 70% and 80% population vaccination coverage for each allocation strategy, with vaccines delivered per 4. We use a baseline TP of 3.6, which corresponds to TP under baseline PHSMs and partial TTIQ.

| Allocation strategy | Eligible population coverage (16+) | | | |
|-----------------------|------------------------------------|-----|-----|-----|
| | 50% | 60% | 70% | 80% |
| Oldest first | 2.1 | 1.7 | 1.5 | 1.3 |
| 40+ years first | 2.1 | 1.9 | 1.6 | 1.3 |
| All adults | 2 | 1.7 | 1.5 | 1.3 |
| Transmission reducing | 2.1 | 1.8 | 1.4 | 1.3 |

Table 6. Percentage of time high PHSM would need to be in place for long-term control, with reversion to low PHSM at other times, for 50%, 60%, 70% and 80% population coverage achieved under the three age-based allocation strategies. These scenarios assume partial TTIQ effectiveness, under high caseloads. Standard age (60+) and dosing interval (12 weeks) recommendations are assumed for AZ vaccine.

| Allocation strategy | Eligible population coverage (16+) | | | |
|-----------------------|------------------------------------|-----|-----|-----|
| | 50% | 60% | 70% | 80% |
| Oldest first | 82% | 49% | 18% | 0% |
| 40+ years first | 89% | 67% | 39% | 2% |
| All adults | 75% | 46% | 22% | 0% |
| Transmission reducing | 87% | 52% | 10% | 0% |

Table 7. Percentage of time high PHSM would need to be in place for long-term control, with reversion to low PHSM at other times, for 50%, 60%, 70% and 80% population coverage achieved under the three age-based allocation strategies. These scenarios assume optimal TTIQ effectiveness, under high caseloads. Standard age (60+) and dosing interval (12 weeks) recommendations are assumed for AZ vaccine.

| Allocation strategy | Eligible population coverage (16+) | | | |
|-----------------------|------------------------------------|-----|-----|-----|
| | 50% | 60% | 70% | 80% |
| Oldest first | 42% | 9% | 0% | 0% |
| 40+ years first | 49% | 27% | 0% | 0% |
| All adults | 35% | 6% | 0% | 0% |
| Transmission reducing | 47% | 12% | 0% | 0% |

263 for different levels of vaccine coverage and intensity of case finding and management strategies, with
264 corresponding costs of these restrictions as estimated by Treasury shown on the right of the figure
265 [13]. These combined outputs demonstrate the substantive cost savings associated with avoidance of
266 lockdown and provided additional justification for delaying reopening until achieving 70% threshold
267 vaccine coverage. The overlay of some degree of social measures at this threshold supported transmission
268 reduction and helped to maintain the effectiveness of an active case finding strategy focused on minimising
269 health impacts. At 80% coverage these restrictions could be eased without any envisaged lockdown
270 requirement.

271 DISCUSSION

272 This work formed the basis of a significant contribution to easing of COVID-19 restrictions in Australia
273 in late 2021 by providing a structured framework to explore the effect of management decisions on
274 transmission of SARS-CoV-2 in Australia based on contemporary evidence [13, 14, 15, 16]. Specifically,
275 it covers the pandemic period up to mid-late 2021, during which time the Delta variant became established
276 in several eastern Australian states resulting in imposition of stringent lockdowns to manage transmission
277 and clinical burden, and closure of interstate borders. For those states, our recommendation of a target
278 vaccination level of at least 70% 1 was a pathway out of restrictions and a way to reconnect with ‘COVID-
279 zero’ jurisdictions. In the other states, high vaccine coverage provided confidence that COVID-19 impacts
280 could be mitigated sufficiently to avoid substantive health system and social disruption, and at 80%
281 coverage only minimal social and behavioural measures would be required to support vaccination 1.

282 The scenarios in this study representing a single national COVID-19 epidemic were clearly (and
283 deliberately) artificial and served to inform high level policy strategy. Beyond defining threshold vaccine
284 targets, they highlighted the importance of a combination of timely public health responses (TTIQ)
285 and ongoing social and behavioural measures (PHSMs) to constrain SARS-CoV-2 transmission. It was
286 recognised that at high caseloads, maintenance of optimal TTIQ was likely infeasible. In such instances,
287 jurisdictions retained the flexibility to strengthen PHSMs generally or locally (as envisaged in the National
288 Plan [12]) to regain local epidemic control 3. The required intensity and duration of measures was to be
289 informed by ongoing situational assessment of transmission and its related health impacts [19].

290 In August 2021 when these analyses were first reported, evidence of vaccine efficacy against acquisi-
291 tion and onward spread of infection had raised hopes that equitable vaccine distribution could substantially
292 limit global transmission and burden of COVID-19 disease [33]. However, studies undertaken by multiple

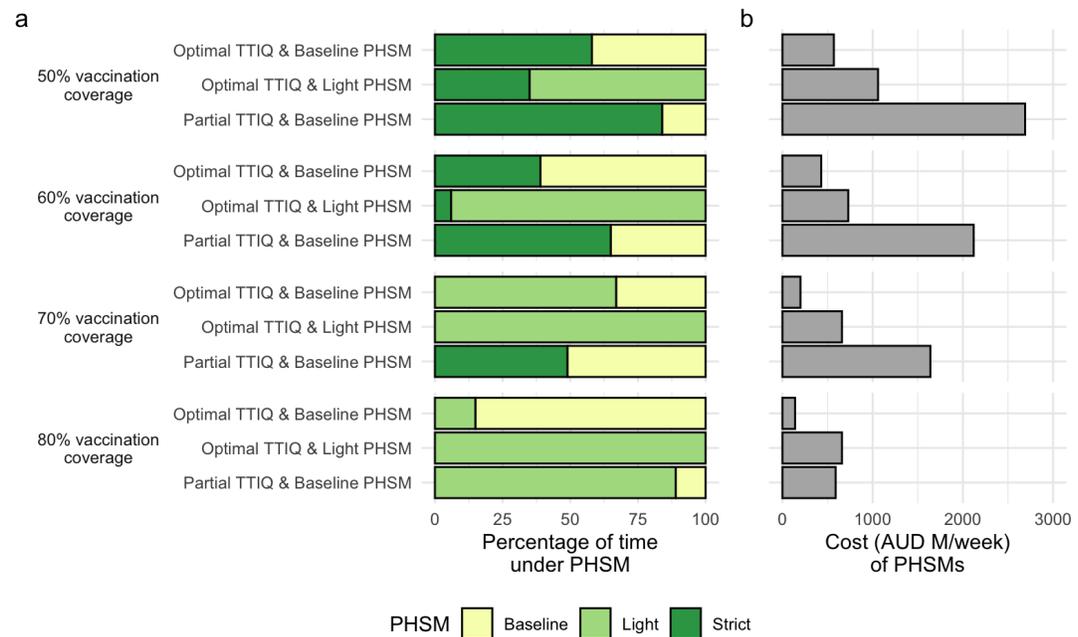

Figure 3. Percentage of time necessary under PHSMs to constrain outbreaks (a) and cost (in millions of Australian dollars per week) of the least expensive PHSM bundle able to constrain outbreaks (b) under each combination of TTIQ effectiveness and ongoing PHSMs, at 50, 60, 70, and 80% vaccination coverage of the 16+ adult population, and an "All adults" vaccine allocation scenario. Data in (a) from S2, S3, S4, and S5, and (b) from [13]

293 modelling groups supporting decision making to ease UK lockdowns during the Delta era similarly
 294 cautioned against the lifting of all restrictions ('freedom day') following achievement of vaccine targets,
 295 given imperfect vaccine protection and potential for resurgence [34]. In support of this position, a rapid
 296 rebound of Delta infections following reopening in the Netherlands had necessitated re-imposition of
 297 social measures within only weeks of easing. At that time, global concern about driving emergence
 298 of further variants remained high and strong suppression strategies were favoured by the World Health
 299 Organisation [35].

300 Our findings were aligned with and benchmarked against the UK modelling reports, including the
 301 recommendation for ongoing social constraints, but were novel in two main aspects. For the majority
 302 of Australian jurisdictions, relaxation of border restrictions would allow importation of infections into
 303 'COVID-zero' settings, requiring high confidence in model recommendations. The use of transmission
 304 potential as a novel metric enabled anticipation of case loads in settings where there were presently none
 305 [10]. Given ongoing global discussions about competing health and economic impacts of COVID-19 and
 306 social measures for its control [36], the accompanying Treasury analyses were highly influential in whole
 307 of government decision making. We are unaware of similar publicly available estimates of the costs of
 308 PHSMs under different levels of vaccine coverage from other country settings.

309 The model assumed fixed efficacy of vaccine protection against transmission and disease at a single
 310 time point and did not incorporate waning immunity. At the time of analysis, longevity of population
 311 experience with COVID-19 vaccines was limited and evidence of the rate of loss of protection was sparse.
 312 Israel was the first country to approve booster doses on July 30 2021, initially for individuals aged 60 and
 313 above. This recommendation was prompted by observation of breakthrough infections following primary
 314 vaccination consistent with waning immunity [37]. Booster requirements were then a contentious issue,
 315 with many arguing that broad provision of a third vaccine dose was unnecessary in highly immunised
 316 populations. There were particular concerns about impacts on supply for global vaccine equity, given
 317 persistently low primary vaccine coverage and access in many low and middle income countries [38].

318 Note that the visualisations and metrics presented in this paper were used to evaluate the general

319 viability of different suites of measures, under a very uncertain future epidemiological situation and period
320 of time. These metrics were not sufficient to calculate the likely morbidity and mortality outcomes of
321 COVID-19 under specific rollout strategies and changes given the dynamic nature of vaccination and
322 transmission. Related work extended our initial findings on transmission potential into an agent based
323 model framework to estimate those impacts and is reported elsewhere [39].

324 It was further recognised that the national COVID-19 epidemic had been, and would continue to
325 be, a ‘fire’ fought on multiple fronts across Australia’s geographically distributed population, largely
326 concentrated in coastal urban cities. We recommended that particular attention be paid to groups in whom
327 socioeconomic, cultural and other determinants were anticipated to result in higher transmission and/or
328 disease outcomes. In addition, achievements of vaccination targets at small area level was critical to
329 ensure equity of program impact, as ongoing outbreaks in under-vaccinated populations were considered
330 likely, and would need to be supported by optimisation of localised public health responses. These issues
331 were the focus of subsequent work [11, 39].

332 In reality, the applicability of these defined thresholds to reopening goals was made redundant by im-
333 portation and rapid transmission of the Omicron SARS-CoV-2 variant in December 2021. Dissemination
334 of this and subsequent immune escape variants has led to global reconsideration of the role of vaccination
335 in the control of COVID-19. Moreover, vaccine protection against severe disease appears more robust
336 and sustained than that against transmission, particularly in the context of waning post-immunisation
337 neutralising antibody titres (REF). This emerging understanding has reoriented strategic vaccine use
338 towards promoting population resilience against severe disease outcomes, rather than transmission reduc-
339 tion. Subsequent work focuses on the implications of variant emergence for deployment of vaccines and
340 other control measures in the era of Omicron and beyond.

341 **ETHICS**

342 The study was undertaken as urgent public health action to support Australia’s COVID-19 pandemic
343 response. The study used data from the Australian National Notifiable Disease Surveillance System
344 (NNDSS) provided to the Australian Government Department of Health under the National Health Security
345 Agreement for the purposes of national communicable disease surveillance. Data from the NNDSS were
346 supplied after de-identification to the investigator team for the purposes of provision of epidemiological
347 advice to government. Contractual obligations established strict data protection protocols agreed between
348 the University of Melbourne and sub-contractors and the Australian Government Department of Health,
349 with oversight and approval for use in supporting Australia’s pandemic response and for publication
350 provided by the data custodians represented by the Communicable Diseases Network of Australia. The
351 ethics of the use of these data for these purposes, including publication, was agreed by the Department of
352 Health with the Communicable Diseases Network of Australia.

353 **ACKNOWLEDGEMENTS**

354 This work forms part of a wider body of work around supporting Australia’s plan to reopen from COVID-
355 19 restrictions (often known in media as ‘the Doherty modelling’). We thank our many colleagues who,
356 while largely locked in their homes, contributed to this large undertaking with unfailing good grace and
357 humour.

358 We also thank many colleagues at Treasury who helped advise and focus this work, in particular
359 including those contributing to [13].

360 This work was directly funded by the Australian Government Department of Health Office of Health
361 Protection. Additional support was provided by the National Health and Medical Research Council of
362 Australia through its Centres of Research Excellence (SPECTRUM, GNT1170960) and Investigator
363 Grant Schemes (JMcV Principal Research Fellowship, GNT1117140; FMS Emerging Leader Fellowship,
364 2021/GNT2010051).

365 This research was supported by The University of Melbourne’s Research Computing Services and the
366 Petascale Campus Initiative.

540 SUPPLEMENTARY MATERIALS

541 Fraction of time in lockdown

542 Where a vaccination scenario leads to either a $TP_1 > 1$ with one PHSM bundle and $TP_2 < 1$ with a more
543 stringent bundle, the long-term average TP can be maintained at 1, i.e. with daily case counts neither
544 growing nor shrinking over the long term, by alternating between the two PHSM bundle states. Whilst
545 the first PHSM bundle is in place cases will grow, and whilst the more stringent bundle is in place cases
546 will shrink, leading to an oscillation of case counts around some average level S_1 . This reflects a strategy
547 that might be used to keep cases below a health sector capacity limit in the event that there is long-term
548 community transmission and under the necessary simplifying assumption that vaccination coverage is
549 static.

Where $TP_1 > 1$ and $TP_2 < 1$, we can calculate the fraction of time spent under more stringent PHSMs
as:

$$fraction = -\frac{\log(TP_1)}{\log(TP_2) - \log(TP_1)} \quad (S1)$$

550 Where $TP_1 < 1$ the fraction is zero, and as the more stringent PHSM bundle is not needed. Where $TP_2 > 1$
551 no fraction exists, because even the more stringent PHSM bundle could not control transmission.

552 Note that this fraction of time under more stringent PHSMs is independent of the sequence or duration
553 of the periods under more stringent restrictions; a strategy of rapid switching on and off of restrictions, or
554 one of alternating long periods with or without restrictions would both lead to long-term maintenance
555 of $TP = 1$, provided the fraction of time in each condition is the same and that daily case numbers are
556 either growing or contracting exponentially (i.e., no significant susceptible depletion alters the growth
557 rate), e.g. S_1 . However for practical reasons, a rapid switching between states is unlikely to be used. The
558 overall number of cases (as opposed to the long-term average TP) will however be dependant on the rate
559 of switching, but it is assumed in all calculations in this paper that switching is sufficient to maintain total
560 case numbers below a level which would result in overwhelming of the public healthcare system.

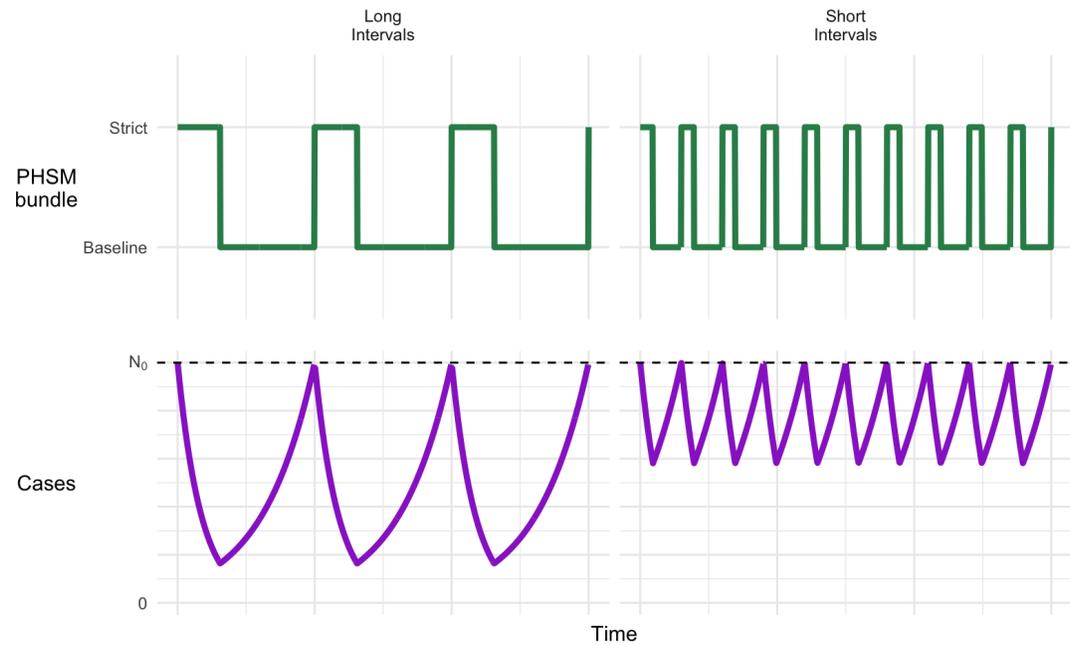

Figure S1. Example of how daily cases may fluctuate over time in response to stringency of PHSMs using 80% vaccination coverage, partial TTIQ and reversion to baseline PHSMs, with either long or short intervals between switching PHSMs. In this example, to maintain a stable $TP \leq 1$ over time requires strict PHSMs for $\geq 31\%$ of the time $3, S2$. Starting with strict PHSMs as here results in cases fluctuating below the initial daily case number (N_0 , dotted line). The length of intervals under respective PHSMs (left vs. right) will not alter the overall average TP (though may affect total case numbers).

561 **Transmission matrix**

562 Population mixing within and between age groups is configured based on widely accepted social contact
563 matrices published by [29]. It has been expanded to include an 80+ age class (assumed to have the same
564 mixing rates as 75-79 years) S2. Age-specific susceptibility and transmissibility estimates from [30] are
565 used and transmission rates have been calibrated to our baseline population-wide TP of 3.6.

566 The greatest mixing intensities are anticipated between individuals aged from 15-24 years, remaining
567 high through adults of working age. While intense school-based mixing is anticipated between children
568 aged 5-14, the transmission matrix accounts for the relatively low observed infectiousness of this age
569 group, associated with a high proportion of asymptomatic infections.

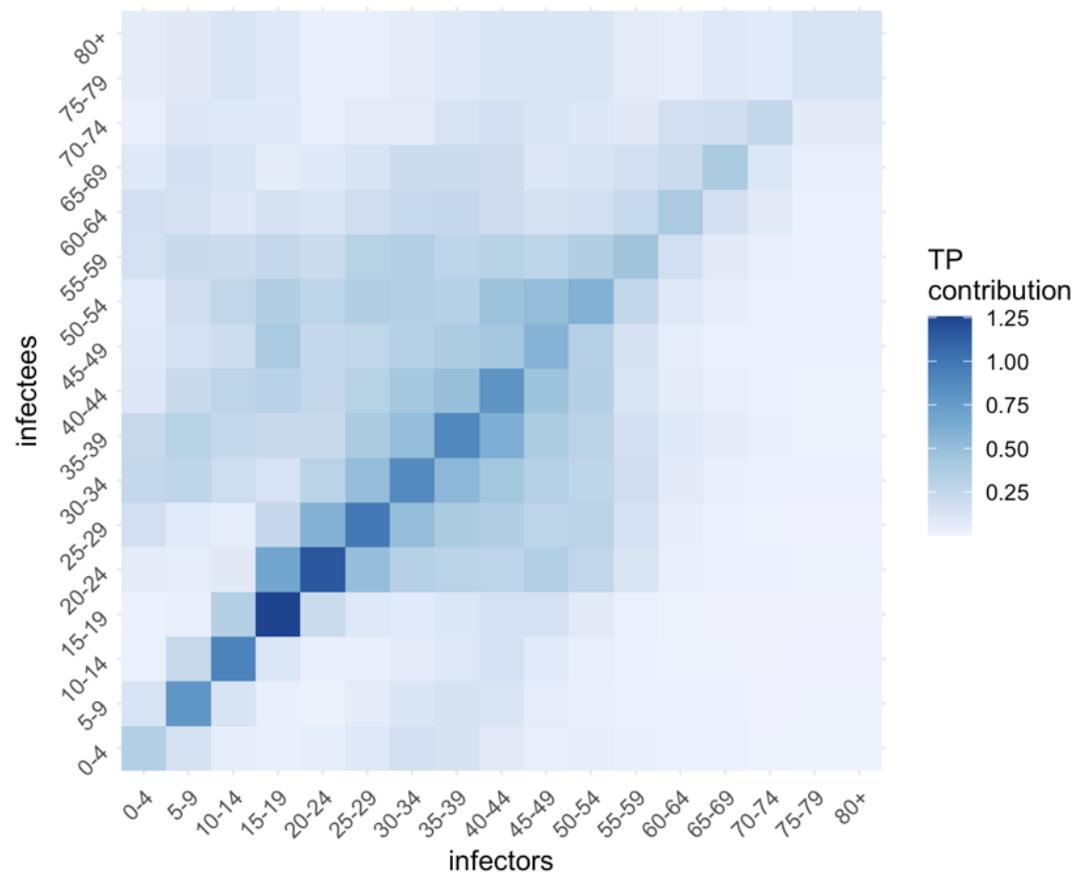

Figure S2. Age-based transmission matrix derived from [29].

570 **Supplementary figures and tables**

Table S1. Detailed description of measures implemented under PHSM ‘bundles’.

| | High PHSM | Medium PHSM | Low PHSM | Baseline PHSM |
|-----------------------|--|---|---|--|
| Reference period | VIC 23 August 2020 | NSW 1 July 2021 | NSW 23 August 2020 | NSW March 2021 |
| Stay at home orders | Stay-at-home except essential purposes | Stay-at-home except for work, study and essential purposes | No stay-at-home orders | No stay-at-home orders |
| Density restrictions | 4 m ² rule | 2 m ² rule | 2 m ² rule | 2 m ² rule |
| Retail trade | Non-essential retailers and venues closed to public. Take away and home delivery only | Increased retail activity, subject to density restrictions. Seated dining for small groups at cafes/restaurants | Social distancing rules apply. Larger groups allowed. | Social distancing rules apply |
| Work | Only workplaces categorised as permitted work allowed to operate on-site and subject to restrictions | Work from home if possible, capacity limits and restrictions on office space apply | Return to work, but social distancing and capacity restrictions on office space apply | 1.5 m ² rule |
| Schools and childcare | Closed – remote learning only | Closed or graduated return | Open | Open |
| Capacity restrictions | No gatherings - Non-essential venues etc closed. | Indoor venues closed. Capacity limits restricted to small groups outdoors | Recreational activities allowed and venues open but social distancing and capacity limits apply | Large sporting venues to operate at 70 per cent capacity |
| Travel restrictions | Essential movements only within 5 or 10 km radius. No intra- or inter-state travel | Non-essential travel limited. No intra- or inter-state travel | No travel restrictions. Interstate travel allowed | No travel restrictions. Interstate travel allowed |
| Other | Curfew. No household visitors and 2-person limit on exercise | 5 visitors to household and limited outdoor gatherings e.g., 10 people | Requirements for record keeping, COVID-safe plans etc. | |

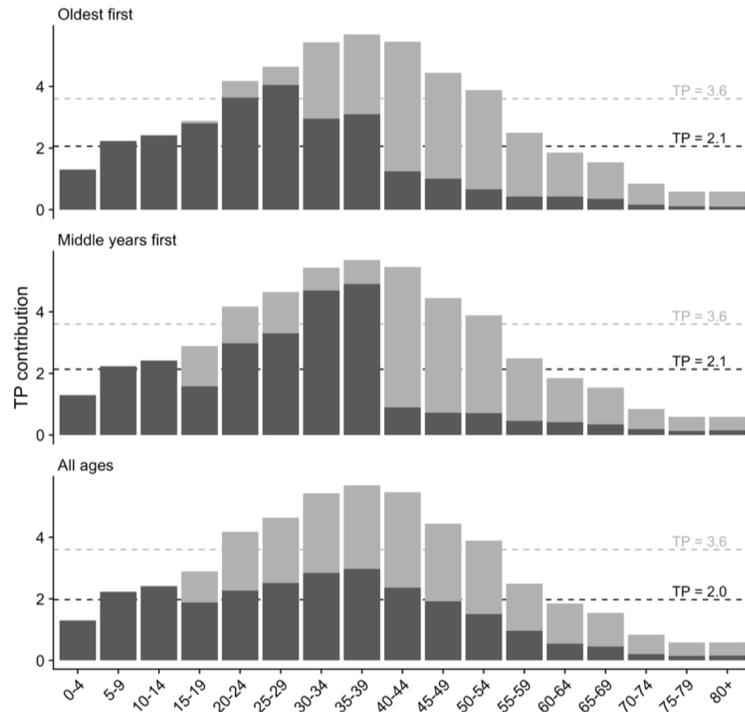

Figure S3. mpact of the four different vaccine allocation strategies on TP by age category, resulting in the overall TP achieved by 50% age eligible population coverage. Dark grey represents TP contribution after vaccination, and light grey in the absence of vaccination. Dashed lines correspond to whole population differences in TP with age-group interactions included (is marginal contribution of each age-group / column sums of transmission matrix)

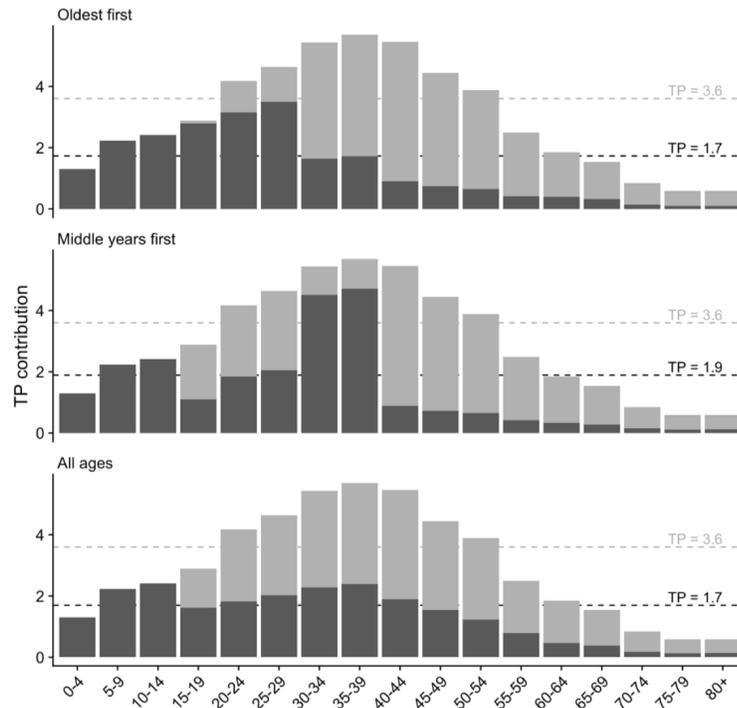

Figure S4. Impact of the four different vaccine allocation strategies on TP by age category, resulting in the overall TP achieved by 60% age eligible population coverage. Dark grey represents TP contribution after vaccination, and light grey in the absence of vaccination. Other coverage levels (50, 60 and 80% are in figures S2a-c). Dashed lines correspond to whole population differences in TP with age-group interactions included (is marginal contribution of each age-group / column sums of transmission matrix)

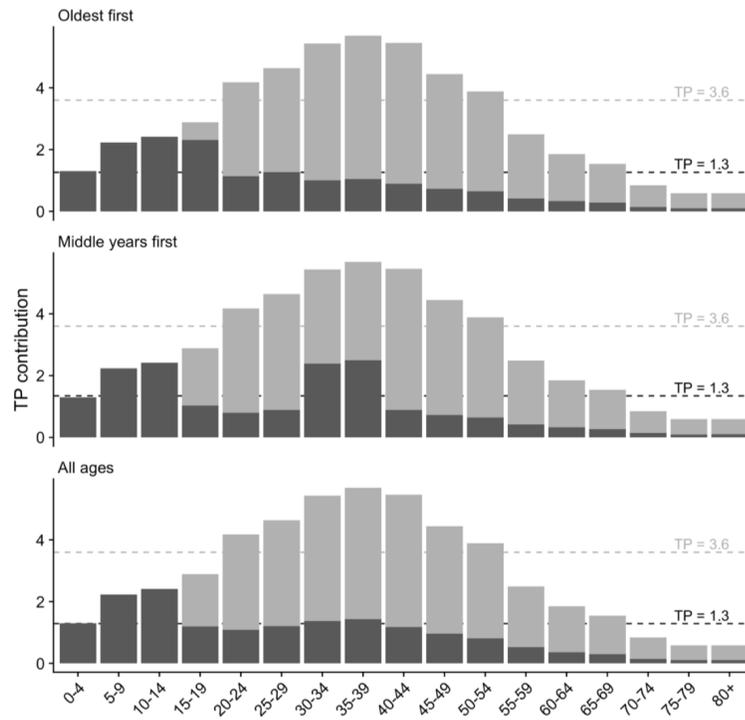

Figure S5. mpact of the four different vaccine allocation strategies on TP by age category, resulting in the overall TP achieved by 80% age eligible population coverage. Dark grey represents TP contribution after vaccination, and light grey in the absence of vaccination. Dashed lines correspond to whole population differences in TP with age-group interactions included (is marginal contribution of each age-group / column sums of transmission matrix)

Table S2. Proportion of time lockdowns are needed to constrain transmission when the TTIQ public health response is only partially effective, due to high caseloads

| Vaccine coverage | Allocation Scenario | Light restrictions only | Moderate lockdowns only | Strict lockdowns only |
|------------------|---------------------|------------------------------------|------------------------------------|-----------------------|
| 50% | Oldest first | Not possible to constrain outbreak | Not possible to constrain outbreak | 89% |
| | 40+ years first | Not possible to constrain outbreak | Not possible to constrain outbreak | 93% |
| | All adults | Not possible to constrain outbreak | Not possible to constrain outbreak | 84% |
| 60% | Oldest first | Not possible to constrain outbreak | Not possible to constrain outbreak | 67% |
| | 40+ years first | Not possible to constrain outbreak | Not possible to constrain outbreak | 78% |
| | All adults | Not possible to constrain outbreak | Not possible to constrain outbreak | 65% |
| 70% | Oldest first | Not possible to constrain outbreak | 77% | 47% |
| | 40+ years first | Not possible to constrain outbreak | 99% | 60% |
| | All adults | Not possible to constrain outbreak | 81% | 49% |
| 80% | Oldest first | 82% | 47% | 29% |
| | 40+ years first | Not possible to constrain outbreak | 59% | 36% |
| | All adults | 89% | 51% | 31% |

Table S3. Proportion of time lockdowns are needed to constrain transmission when the TTIQ public health response is optimally effective.

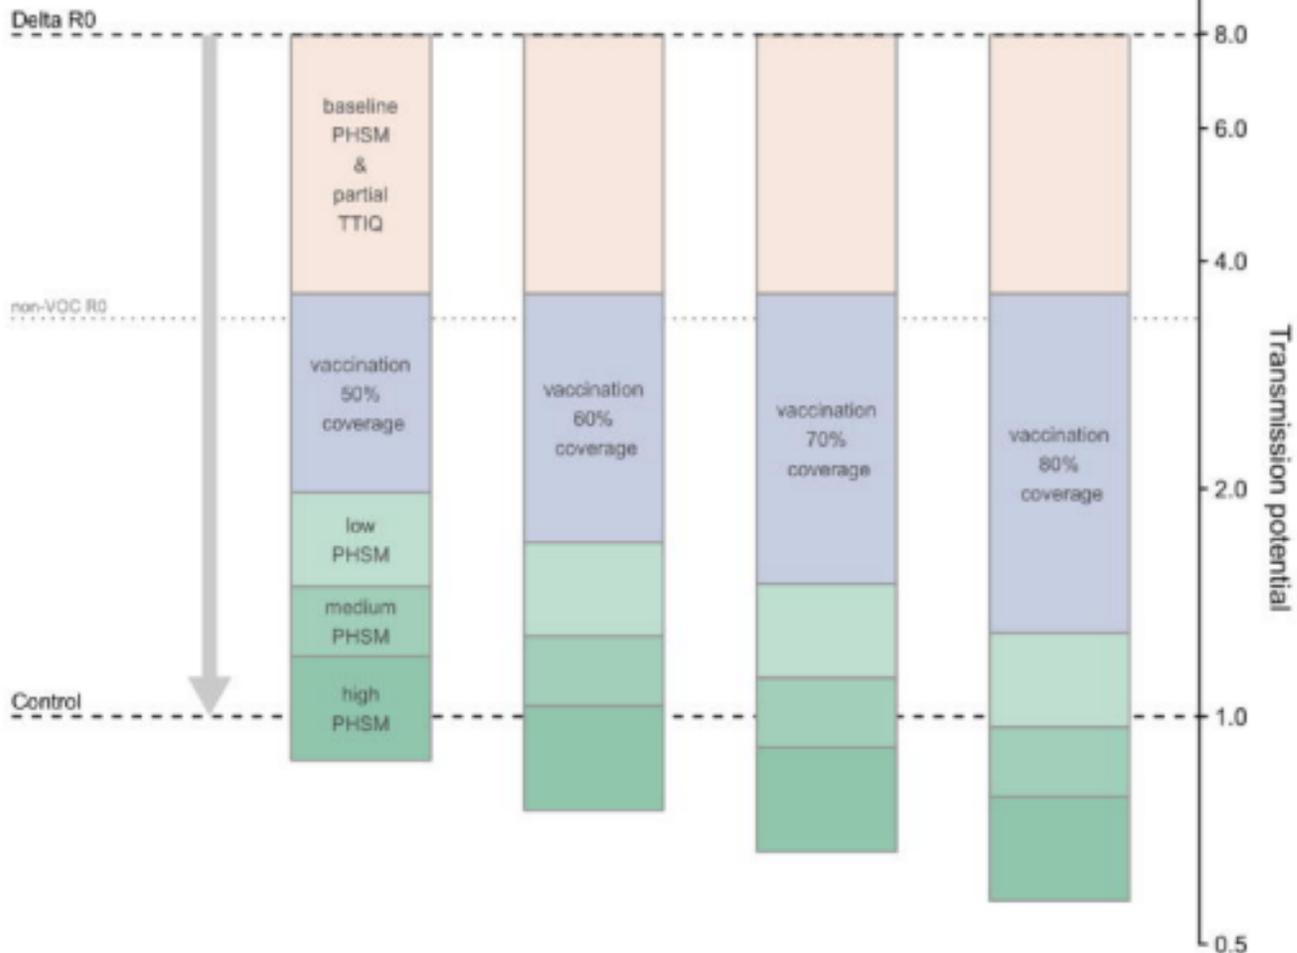

| Vaccine coverage | Allocation Scenario | Light restrictions only | Moderate lockdowns only | Strict lockdowns only |
|------------------|---------------------|------------------------------------|------------------------------------|-----------------------|
| 50% | Oldest first | Not possible to constrain outbreak | Not possible to constrain outbreak | 63% |
| | 40+ years first | Not possible to constrain outbreak | Not possible to constrain outbreak | 67% |
| | All adults | Not possible to constrain outbreak | 94% | 58% |
| 60% | Oldest first | Not possible to constrain outbreak | 67% | 41% |
| | 40+ years first | Not possible to constrain outbreak | 86% | 52% |
| | All adults | Not possible to constrain outbreak | 64% | 39% |
| 70% | Oldest first | 60% | 34% | 21% |
| | 40+ years first | 97% | 56% | 34% |
| | All adults | 67% | 38% | 23% |
| 80% | Oldest first | 7% | 4% | 3% |
| | 40+ years first | 29% | 17% | 10% |
| | All adults | 15% | 8% | 5% |

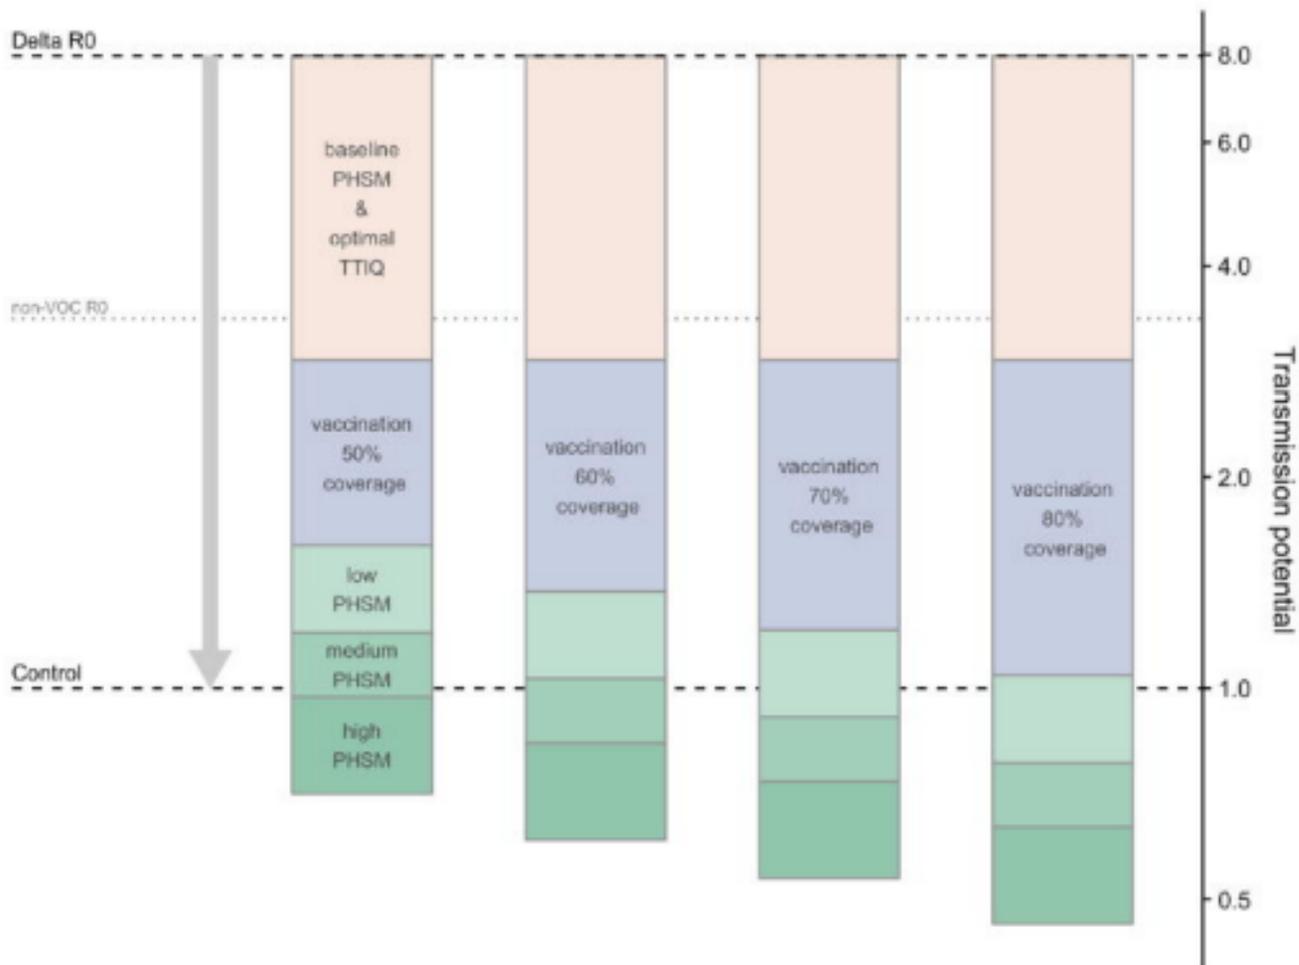

Table S4. Proportion of time lockdowns needed to constrain transmission when the TTIQ public health response is only partially effective, due to high caseloads, and where light restrictions are always in place.

| Vaccine coverage | Allocation Scenario | Moderate lockdowns only | Strict lockdowns only |
|------------------|---------------------|------------------------------------|-----------------------|
| 50% | Oldest first | Not possible to constrain outbreak | 82% |
| | 40+ years first | Not possible to constrain outbreak | 89% |
| | All adults | Not possible to constrain outbreak | 75% |
| 60% | Oldest first | Not possible to constrain outbreak | 49% |
| | 40+ years first | Not possible to constrain outbreak | 67% |
| | All adults | Not possible to constrain outbreak | 46% |
| 70% | Oldest first | 46% | 18% |
| | 40+ years first | 97% | 39% |
| | All adults | 55% | 22% |
| 80% | Oldest first | 0% | 0% |
| | 40+ years first | 4% | 2% |
| | All adults | 0% | 0% |

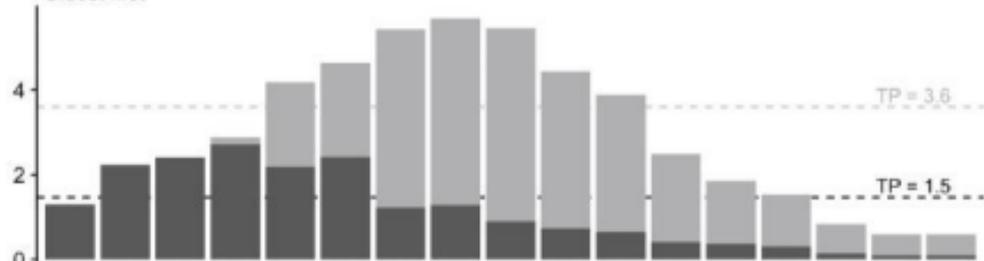

Table S5. Proportion of time lockdowns needed to constrain transmission when the TTIQ public health response is optimally effective and where light restrictions are always in place.

| Vaccine coverage | Allocation Scenario | Moderate lockdowns only | Strict lockdowns only |
|------------------|---------------------|------------------------------------|-----------------------|
| 50% | Oldest first | Not possible to constrain outbreak | 42% |
| | 40+ years first | Not possible to constrain outbreak | 49% |
| | All adults | 87% | 35% |
| 60% | Oldest first | 23% | 9% |
| | 40+ years first | 66% | 27% |
| | All adults | 15% | 6% |
| 70% | Oldest first | 0% | 0% |
| | 40+ years first | 0% | 0% |
| | All adults | 0% | 0% |
