Abstract

Cardiac homeostasis relies on the appropriate provision of nutrients to the working myocardium. EPHB4 is required for the maintenance of vascular integrity and correct fatty acid transport uptake in the heart via regulating the caveolar trafficking of the fatty acid receptor CD36. In the mouse, endothelial specific loss-of-function of the receptor EphB4, or its ligand ephrin-B2, induces Dilated Cardiomyopathy (DCM) like defects. Now, we have identified six new *EPHB4* variants with deleterious potential in a cohort of 573 DCM patients. Similar to the EphB4 mutant mice, *EPHB4* variants carrying patients show an altered expression pattern of CD36 and CAV1 in the heart. For the first time, our data identifies EPHB4 mutations in DCM patients. This observation supports the notion that the Eph-ephrin signalling pathway, and in particular the receptor EPHB4, plays a role in the development of DCM in human patients.

Key words: Dilated cardiomyopathy, EPHB4, CAV1, CD36

Introduction

Dilated cardiomyopathy (DCM) is one the most common type of heart disease with an estimated prevalence of 1:2500 in the general population¹. DCM patients are characterized by the dilation of the left ventricle and contractile dysfunction². The definition of DCM excludes ischemic heart disease, although ischemic events as induced by myocardial infarction can lead to similar remodelling processes and contractile dysfunction resembling DCM³.

The most common causes of DCM underlie inflammation, nutritive-toxic influence, or metabolic disorders⁴ but mutations on genes encoding cytoskeletal, sarcomere or nuclear envelope proteins account for about 35% of DCM cases². Increasing evidence shows that heart disease is associated with microvascular dysfunction⁵. Endothelial cell CD36 is required for the uptake of circulating fatty acids into the cardiac muscle⁶. In the mouse, interference with endothelial nutrient transport resulted in reduced cardiac function⁷. Specifically, endothelial specific deletion of Ephrin type-B receptor 4 (EPHB4), or its ligand ephrin-B2, induces cardiac remodelling and a phenotype that mimics human DCM features and development⁸. Mechanistically, EPHB4 deficient endothelial cells are characterized by compromised caveolar function and reduced Caveolin 1 (CAV1) phosphorylation. Caveolae are required for the correct membrane translocation of the fatty acid translocase FAT/CD36⁹ and fatty acids are used by cardiomyocytes to obtain about 50% to 70% of their energy¹⁰.

In the present study, we identify six new EPHB4 mutations in a cohort of DCM patients. These patients, similar to the EPHB4 mutant mice, show dysregulated expression of CAV1 and CD36 although in the studied patients, this was observed in the cardiomyocytes. Our results confirm a crucial role of the Eph-ephrin signalling pathway in DCM.

Methods

Human samples

All participants in the DZHK-TORCH and in the registry of the Institute for Cardiomyopathies Heidelberg registry have given written informed consent and the study was approved by the ethic committees of the participating study centres. A peripheral blood sample was collected from each participant. SOP Quality Training and monitoring were performed regularly as described¹¹.

Immunohistochemistry

Human sample biopsies were fixed with 4% PFA and embedded in paraffin. Rabbit anti-CAV1 (1:100, 3238S, Cell Signaling, RRID:AB_2072166), mouse anti-CD36 (1:50, C114979, LSBio), and Biotinylated Ulex (1:50, B-1065, Vector, RRID:AB_2336766) were applied overnight, followed by a 1 hour incubation at room temperature with donkey anti rabbit Alexa Fluor 555 (1:200, A31572, Invitrogen, RRID:AB_162543), donkey anti mouse Alexa Fluor 488 (1:200, A21202, Invitrogen, RRID:AB_141607), and Streptavidin Alexa Fluor 647 (1:200, S32357, Invitrogen). Researchers were blind to patient genotype and status for immunohistochemistry and analysis. 6 EPHB4 variant carrying DCM patients, 6 DCM patients with wild type EPHB4 and one healthy control biopsy.

Single-nucleus-RNA-sequencing

The single-nucleus-RNA-sequencing data set generated in the paper by Nicin et al.¹² was used to explore *EPHB4* expression in human cardiac cells.

Results

To assess if EPHB4 mutations might play a role in human heart failure, we analysed the EPHB4 sequences of in total 573 DCM patients, which were either enrolled in the **TranslatiOnal Registry for CardiomyopatHies-Plus** (TORCH-Plus-DZHK21)¹³, or recruited at the Institute for Cardiomyopathies Heidelberg (ICH). In six patients, of which histology was also available, we found six new EPHB4 variants (**Table 1**). Three of the newly identified variants are located in the extracellular domain of EPHB4, two of them in the ligand binding domain of the protein and

another one on the cysteine rich domain before the two fibronectin type III domains. The other three variants are located in the intracellular part of the EPHB4 protein, in the tyrosine kinase domain (**Figure 1A**). In four of these patients we did not detect any mutation in genes previously related to DCM while in the other two patients we could also detect a truncating *RMB20* or *TTN* variants. The Combined Annotation Dependent Depletion (CADD) score of these variants (21,64 [IQR 19,41-23,50]) indicates that the variants found in this study have a high potential to be deleterious as CADD scores >20 indicate the top 1% of predictably deleterious variants. In order to understand whether these new EPHB4 variants could be implicated in the disease, we analysed DCM patients carrying the heterozygous EPHB4 variant and DCM patients with no such variant. We furthermore compared the results with a biopsy obtained from a healthy donor. The basal characteristics of the patients can be found on **Table 2**.

Histological analysis of cardiac biopsies obtained from these patients compared to biopsies from DCM patients with reference genotype and healthy donors revealed that the expression of CD36 and CAV1 is altered in DCM patients. CD36 is highly expressed in the capillaries and in the membrane of cardiomyocytes of healthy hearts, while CAV1 can be detected in the capillary endothelial cells (**Figure 1B**). In DCM patients which carry a wild type EPHB4 sequence, we noted that the expression of CD36 is abrogated and a disorganized expression of CAV1 can be observed in the cardiomyocytes (**Figure 1C**). In the *EPHB4* variant carriers, the expression of CD36 is reduced in the membrane of cardiomyocytes but colocalizes with CAV1 in accumulated vesicle structures in the cardiomyocytes, suggesting impaired CD36 caveolar transport (**Figure 1D, arrowheads**). Interestingly, and different to the data on mouse ⁸, the miss localization of CAV1 and CD36 was observed in cardiomyocytes.

Analysis of available human cardiac single-nuclei-RNA-sequencing¹² revealed that *EPHB4* is also expressed in human cardiomyocytes (**Figure 1E**) suggesting that EPHB4 may control CD36 localization also in cardiomyocytes-

Discussion

Our results suggest that the dysfunction of the EPHB4 receptor and its regulation of caveolae trafficking required for fatty acid uptake as a potential cause for DCM in human patients. Furthermore, our results stress the importance of the endothelial CD36 in the onset of cardiac disease as all DCM patients show a downregulation of CD36 in the endothelium and warrant a more detailed assessment of genes involved in vascular function¹⁴. Nevertheless, although more abundantly expressed in endothelial cells, CD36 is also expressed in cardiomyocytes¹⁵ and its loss in cardiomyocytes has already been related with the progression of heart failure¹⁶. There are different molecular mechanisms that can regulate the expression and cellular localization of CD36. CD36 expression is upregulated by the nuclear hormone transcription factor PPAR- γ and cytokines like CSF and IL4. In the other hand, LPS and dexamethasone downregulate its expression. In microvascular endothelial cells, CD36 is downregulated by lysophosphatidic acid. Glycosylation also impacts CD36 expression levels, as does lipid acylation of both the N-terminal and C-terminal intracellular domains (reviewed in¹⁷). We hypothesize that mutations or alteration on these pathways in the heart, similar to EPHB4, may also cause DCM and should be further studied.

Cardiomyocytes are the cells responsible for generating contractile force in the heart and were traditionally at the center of interest in genetic studies. However, only about a third of DCM cases can be explained by mutations on structural cardiomyocyte genes². This study suggests that mutations in genes crucial for cell to cell signalling may contribute to DCM. Attempts to use single-cell- and single-nucleus-RNA-sequencing of cardiac tissue of patients¹⁸ to identify potential genes and pathways in the other cell types just started and certainly will enrich our understanding of the multi-cellular communication that is necessary to maintain cardiac health.

Our analysis identified several variants in EPHB4 in a cohort of DCM patients. According to the CADD score prediction, all these variants have a deleterious potential. During Eph-ephrin

signalling, the binding of the ligand induces Eph receptor heterotetramers to initiate the signalling via Eph–Eph cis interactions¹⁹. Thus, variant EPHB4 molecules could have a dominant negative effect on these heterotetramers explaining why the presence of one variant copy in the DCM patients of our cohort would be sufficient to abrogate the function of the protein. The histology analysis of the cardiac biopsies revealed that, independently of where in EPHB4 the variant was detected, the EPHB4 variant carrying patients show similar histological features with CD36 and CAV1 colocalizing in vesicular structures and are different to the other DCM patients with a wild type EPHB4. This observations includes the two patients that carry variants in other DCM related genes. Although we can't discard the contribution of the variants in other genes in two of the patients, this study further supports, the importance of EPHB4 regulating CD36 caveolar trafficking to the membrane, whether this happens in endothelial cells or cardiomyocytes, maintaining cardiac homeostasis in humans and its implication on DCM. Recent studies suggest that Eph receptor genes, including *EPHB4*, were downregulated in hypertrophic human hearts¹² suggesting that a transcriptional or post transcriptional down-regulation of Eph receptors might also contribute to acquired forms of heart failure. Interestingly, beyond its function in the cellular membrane, circulating EPHB4 is associated with poor prognosis in heart failure²⁰.

Finally, this study not only confirms the crucial role of EPHB4 in the heart, but it also corroborates the importance of CD36 and CAV1 for the cardiac health, and has the potential to improve diagnosis and risk stratification tools for DCM. In addition, as other genes crucial for fatty acid transport may be involved in cardiac disease, this study may help identify new diagnostic or therapeutic targets.

Funding

The study was supported by the German Centre for Cardiovascular Research (DZHK). Grant UA.0004.21 to G.L.

Ethics approval and consent to participate

All participants in the DZHK-TORCH and in the registry of the Institute for Cardiomyopathies Heidelberg registry have given written informed consent and the study was approved by the ethic committees of the participating study centres.

Author Contribution

GL and SD contributed to the conception and design of the research. GL analyzed data, acquired funding and managed the project. MMR, performed immunohistochemistry. SFG analyzed the single-nucleus-RNA-sequencing. JT, CR, JH, FSH and BM analyzed the databases and provided histology samples of DCM patients. GL and SD wrote the paper.

Competing interests

JT received DZHK third party funding from TORCH and TORCH PLUS. The author is also participates in the Internal and external monitoring of TORCH registry. The author has no other competing interests to declare. BM received DZHK third party funding from TORCH and TORCH PLUS. The author is also participates in the Internal and external monitoring of TORCH registry and acts as a speaker for the 'Cardiomyopathy working group DGK'. The author has no other competing interests to declare.
