1 **ABSTRACT**

2

3 **Aims/hypothesis.** Observational evidence suggests a shared etiology between impaired
4 glucose tolerance, cardiovascular risk, and fertility problems. We aim to establish whether
5 impaired glucose tolerance (as measured by fasting glucose, glycated hemoglobin, and
6 fasting insulin) and cardiovascular disease risk (as measured by LDL cholesterol, HDL
7 cholesterol, triglycerides, systolic blood pressure, and diastolic blood pressure) are causally
8 related to infertility (having tried to conceive for ≥ 12 months or used assisted reproduction
9 technologies to conceive) by Mendelian randomization (MR) analyses in women and men.

10 **Methods.** We conducted two-sample MR analyses, in which we used genome-wide
11 association summary data that were publicly available for the cardiometabolic risk factors,
12 and sex specific genome-wide association studies of infertility conducted in the Norwegian
13 Mother, Father, and Child Cohort Study (68,882 women [average age 30, involved in 81,682
14 pregnancies] and 47,474 of their male partners [average age 33, 55,744 pregnancies]). We
15 applied the inverse variance weighted method with random effects to pool data across
16 variants and a series of sensitivity analyses to explore genetic instrument validity (we
17 checked the robustness of genetic instruments and the lack of unbalanced horizontal
18 pleiotropy, and we used methods that are robust to population stratification). Findings were
19 corrected for multiple comparisons by the Bonferroni method (8 exposures: p -value <
20 0.00625).

21 **Results.** In women, increases in genetically determined fasting insulin levels were
22 associated with greater odds of infertility (+1 log(pmol/L): OR 1.60, 95% CI 1.17 to 2.18, p -
23 value = 0.003). The results were robust in the sensitivity analyses exploring the validity of MR
24 assumptions and the role of pleiotropy of other cardiometabolic risk factors. There was also
25 evidence of higher glucose and glycated hemoglobin in women (and possibly higher fasting
26 insulin in men) causing infertility, but findings were imprecise and did not pass our p -value
27 threshold for multiple testing. Results for lipids and blood pressure were close to the null,
28 suggesting that these did not cause infertility.

29 **Conclusions/interpretation.** Genetic instruments suggest that higher fasting insulin may
30 increase infertility in women.

52 **RESEARCH IN CONTEXT** (<200 words)

53

54 **What is already known about this subject?**

- 55 • Observational evidence suggests impaired glucose tolerance, higher lipid
56 concentrations, and higher blood pressure is associated with fertility problems.

57

58 **What is the key question?**

- 59 • Are fasting glucose, glycated hemoglobin, fasting insulin, LDL cholesterol, HDL
60 cholesterol, triglycerides, systolic blood pressure, and diastolic blood pressure
61 causally related to infertility in women and men?

62

63 **What are the new findings?**

- 64 • Two-sample Mendelian randomization suggests that higher fasting insulin levels
65 increase the risk of infertility in women. There was also evidence of higher glucose
66 and glycated hemoglobin in women (and maybe higher fasting insulin in men)
67 causing infertility, but results were imprecise and did not pass our p -value threshold
68 for multiple comparisons.
- 69 • Findings for lipids and blood pressure were close to the null, suggesting that these
70 did not have a causal role on infertility.

71

72 **How might this impact on clinical practice in the foreseeable future?**

- 73 • Treatments to lower fasting insulin levels may reduce the risk of infertility in women.

74 **INTRODUCTION**

75

76 Impaired glucose tolerance and other cardiovascular risk factors are related to fertility
77 problems in women [1, 2] and men [3]. However, these associations may be explained by
78 unmeasured or residual confounding (e.g., adiposity) [4]. Mendelian randomization (MR), a
79 method based on genetic instrumental variables, estimates potential causal effects that are
80 unaffected by confounding [4]. Using this methodology, we have previously described that
81 high and low body weight increase the risk of infertility in both sexes [5], while the previously
82 reported association between smoking and infertility may not be causal [6]. The aim of this
83 study was to investigate whether biomarkers of impaired glucose tolerance (fasting glucose,
84 glycated hemoglobin, fasting insulin) and cardiovascular disease risk factors (LDL cholesterol
85 [LDL-C], HDL cholesterol [HDL-C], triglycerides, systolic and diastolic blood pressure [SBP,
86 DBP]) influence the risk of infertility using a two-sample MR-based approach.

87 **METHODS**

88

89 *Population*

90 Our study involved data from the Norwegian Mother, Father and Child Cohort Study (MoBa)
91 [7]. MoBa is a population-based pregnancy cohort study administered by the Norwegian
92 Institute of Public Health. Pregnant women and their partners were recruited at ~18
93 gestational weeks across Norway between 1999-2008. The cohort is composed by 114,500
94 children, 95,200 mothers and 75,200 fathers. Blood samples were obtained from both
95 parents during pregnancy [8]. Details of the MoBa genotyping data and quality control have
96 been previously described [9]. This work is based on a subsample of parents involved in
97 singleton pregnancies with available genotype and infertility information (68,882 women and
98 47,474 men) from version 12 of the quality-assured data files released in May 11, 2022. Our
99 study followed the STROBE checklists for MR and cohort studies.

100

101 *Genetic variants and instrumental variables*

102 We extracted independent SNPs as genetic instruments from the most recent genome-wide
103 association studies (GWASs) on risk factors of impaired glucose metabolism, lipid profile,
104 and blood pressure (see “Data Availability”). Independent SNPs were not in linkage
105 disequilibrium (pairwise $r^2 < 0.01$) and were associated with their phenotypes according to
106 genome-wide significance thresholds. MoBa was not part in any of these GWASs. We used
107 SNPs individually as genetic instruments [10]. SNPs that were used in the analyses are
108 described in **Supplemental Tables 1-8**. The number of SNPs used in each approach is
109 described in **Supplemental Table 9**.

110

111 *Infertility*

112 Infertility was defined as trying to conceive for ≥ 12 months or having used assisted
113 reproductive technologies as previously described [5, 6]. The reference group comprised

114 participants who conceived spontaneously within 12 months. Couples with unplanned
115 pregnancies were excluded.

116

117 *Other variables*

118 We obtained information from both parents on the age at delivery (continuous), years of
119 education (continuous), BMI (continuous), tobacco use (having ever smoked or not), and
120 number of previous deliveries (continuous). We report the maximum values for all continuous
121 variables for those parents who participated in more than one pregnancy in MoBa.

122

123 *Ethical approval*

124 The MoBa study follows the Declaration of Helsinki for Medical Research involving human
125 subjects. The establishment of MoBa and its initial data collection were based on a license
126 from the Norwegian Data Protection Agency and approved by Regional Committees for
127 Medical and Health Research Ethics. The MoBa cohort is now based on the regulations in
128 the Norwegian Health Registry Act. Participants provided written informed consent before
129 joining the cohort. This project was approved by the Regional Committee for Medical and
130 Health Research Ethics of South/East Norway (reference: 2017/1362).

131

132 *Statistical analyses*

133 We described normally distributed continuous variables by means and SDs, non-normally
134 distributed continuous variables by medians and 1st-3rd quartiles, and categorical variables by
135 proportions. We assessed differences in baseline characteristics between parents with and
136 without infertility by unpaired t-tests (normally distributed variables), Mann-Whitney U-tests
137 (non-normally distributed variables), and chi-squared tests (categorical variables).

138 We first performed sex specific GWASs of infertility in MoBa using Scalable and
139 Accurate Implementation of GEneralized mixed models (accounting for kinship and adjusted
140 for the first 20 genetic principal components, genotype batch, and age at reported infertility).
141 We then searched for the SNPs linked to the cardiometabolic risk factors in the summary

142 statistics of the infertility GWASs. Palindromic SNPs with allele frequencies close to 0.5 were
143 excluded. After data harmonization, we estimated the association between the risk factor of
144 interest and infertility using a random effects inverse variance weighted method [10]. We
145 corrected our findings for multiple comparisons (8 exposures) by the Bonferroni method (p -
146 value threshold < 0.00625). Finally, the three key MR assumptions that must be met to obtain
147 valid conclusions in MR analyses [10] (genetic instruments are robustly related to the
148 exposure, there is no confounding of the genetic instrument-outcome associations, and
149 genetic instruments are exclusively linked to the outcome through the exposure of interest)
150 were investigated in detail as described in the **Supplemental Methods**.

151 Analyses were conducted in R Software v. 4.1.2. Code for data management and
152 analysis is available in
153 https://github.com/alvarohernaez/MR_cardiometabolic_infertility_MoBa.

154 **RESULTS**

155

156 *Study population*

157 Our study population consisted of 68,882 women (a total of 81,682 pregnancies) and 47,474
 158 men (55,744 pregnancies) (**Supplemental Figure 1**). Infertility was reported in 12% of the
 159 couples. Participants with infertility were older, had lower educational attainment, greater
 160 mean BMI values, were more likely to have smoked, and were more likely to be trying for a
 161 first pregnancy (**Table 1**).

165 *Cardiometabolic risk factors and infertility*

166 In women, increases in the genetically determined levels of fasting insulin were related to
 167 greater odds of infertility (+1 log(pmol/L): OR 1.60, 95% CI 1.17 to 2.18, *p*-value = 0.003)

168 **(Figure 1)**. We found no evidence that this result was affected by weak instrument bias
 169 (estimated F-statistic: 52.5) or unbalanced horizontal pleiotropy (MR-Egger intercept test p -
 170 value = 0.194; no evidence of between-SNP heterogeneity [Cochran's Q = 55.8, p -value =
 171 0.445; Rucker's Q' = 54.1, p -value = 0.472]; consistency in directionality of estimates in MR
 172 sensitivity methods; consistency between main analyses and those only using the genetic
 173 variants that were unrelated to other risk factors according to the Steiger filtering)
 174 **(Supplemental Table 10)**. Associations of higher maternal fasting glucose and glycated
 175 hemoglobin in women (and maybe fasting insulin in men) with greater infertility odds were
 176 suggested. However, these relationships were imprecise and did not pass our multiple
 177 testing p -value threshold. Lipid and blood pressure associations with infertility were close to
 178 the null **(Figure 1, Supplemental Table 10)**.

179

180 **Figure 1.** MR analyses on the relationship of cardiometabolic risk factors with infertility in
 181 women and men (units differ for each exposure, results are not directly comparable in
 182 magnitude).

183

184 **DISCUSSION**

185

186 In this MR analysis, genetic instruments suggest that higher concentrations of fasting insulin
187 increase the risk of infertility in women. An association between higher fasting glucose and
188 glycated hemoglobin in women (and maybe higher fasting insulin in men) and higher risk of
189 infertility is also suggested but analyses in larger numbers of participants are needed to
190 confirm this. Hyperinsulinemia, a marker of insulin resistance, and glucose intolerance are
191 common in women with polycystic ovary syndrome, which is a cause of infertility [11].
192 Hyperinsulinemia is also linked to follicular dysplasia and impaired synthesis of sexual
193 hormones in the follicle (less progesterone, lower availability of follicle stimulating hormone,
194 and more androgens) [12, 13]. Our findings support hyperinsulinemia as a cause of infertility
195 in women. The lack of robust statistical evidence for an effect of lipids and blood pressure on
196 infertility suggests that previous observational results [1-3] may have been influenced by
197 residual confounding.

198 Our work has several strengths. MR studies exploring the relationship between
199 cardiometabolic risk factors and a clinical definition of fertility have been lacking. Our findings
200 were based on a relatively homogeneous population, and together with a thorough
201 evaluation of compliance with MR assumptions, our findings appear robust. However, our
202 study has some limitations. First, infertility is a couple-dependent measure. Thus, we could
203 not establish if underlying causes of infertility were in the woman, man, or both. Second,
204 MoBa only recruited couples who had conceived. Therefore, studies with couples who never
205 conceived are warranted. Third, we did not have data on circulating levels of cardiometabolic
206 risk factors in MoBa and there was no GWAS of infertility with available summary data
207 across the genome. Thus, we opted to undertake a GWAS of infertility in MoBa (with no
208 independent replication) and a two-sample MR using summary results from publicly available
209 GWAS of the exposures and those from our MoBa GWAS. Our outcome GWAS is relatively
210 small. Thus, we have highlighted some suggested results that were clinically relevant but did
211 not pass multiple testing. Our findings need replication in two-sample MR using results from

212 a larger GWAS of infertility and/or a large independent sample in which one-sample MR
213 could be undertaken. Fourth, no sex-specific genetic instruments were available in the
214 largest GWASs on cardiometabolic risk factors, and we had to assume that there were no
215 sex differences in the genetic instruments for exposures. However, this assumption may
216 imply a violation of the first MR principle. Finally, the characteristics of our study sample
217 limits the generalizability of our results to other populations, particularly to populations of
218 genetic ancestries other than European.

219 In conclusion, genetic instruments suggest a role of hyperinsulinemia and possibly
220 glucose intolerance on infertility in women. If further research in larger samples and with sex-
221 specific exposure instruments support our findings, preventing hyperinsulinemia may be a
222 means of reducing fertility problems in women.

5 **MR assumptions and sensitivity analyses**

6 There are three key assumptions in MR: 1) genetic instruments are robustly related to the
7 exposure, 2) there is no confounding of the genetic instrument-outcome associations, and 3)
8 genetic instruments are exclusively linked to the outcome through the exposure of interest. If
9 violated, MR conclusions may be invalid [1].

10 In relation to the first assumption, we estimated the robustness of our genetic
11 instruments as the mean F-statistic (average $\beta^2/\text{standard error}^2$ across all SNPs; F-
12 statistics < 10 suggest a weak genetic instrument) [1]. Regarding the second assumption, we
13 reduced the potential confounding of the genetic instrument-outcome association due to
14 population stratification by: 1) selecting our genetic instruments from GWASs performed in
15 populations of European ancestry; 2) conducting MR analyses using GWASs adjusted for
16 genetic principal components [2].

17 Genetic instruments that are related to other risk factors for the outcome different
18 than the exposure of interest (horizontal pleiotropy) violate the third MR assumption [3]. We
19 checked the presence of horizontal pleiotropy by procedures based on sensitivity MR
20 methods (MR-Egger, weighted median, and weighted mode) [4]. It can be identified if: 1) a
21 non-zero intercept is present in the MR-Egger method; 2) there is no concordance among
22 MR estimates in inverse variance weighted and the alternative methods; 3) and between
23 SNP heterogeneity is found according to the Cochran's Q and the Rücker's Q' [4]. Some
24 associations were affected by horizontal pleiotropy, possibly due to the high inter-relation
25 among cardiometabolic risk factors. We thus used the Steiger filtering to determine which
26 SNPs explain more variation in our exposure of interest than in the rest of variables related to
27 it (these SNPs are less susceptible of biasing findings due to horizontal pleiotropy) [4]. For
28 example, 71 of the SNPs for fasting glucose explained more variability in fasting glucose

29 than in the other risk factors considered (the rest of risk factors [glycated hemoglobin, fasting
30 insulin, LDL-C, HDL-C, triglycerides, SBP, DBP] plus BMI and ever smoking) and were
31 retained after the filtering. We repeated MR analyses using exclusively the SNPs that passed
32 the filtering process.
