Short title: Food Insecurity amid COVID-19 Lockdowns in Ethiopia

ABSTRACT

Objective The COVID-19 pandemic was associated with widespread social disruptions, as governments implemented lockdowns to quell disease spread. To advance knowledge of consequences for households in lower-income countries, we examine food insecurity during the pandemic period. **Design** Cross-sectional study using logistic regression to examine factors associated with food insecurity. Data were collected between August and September of 2021 through a Health and Demographic Surveillance System (HDSS) using a survey instrument focused on knowledge regarding the spread of COVID-19; food availability; COVID-19 related shocks/coping; under-five child healthcare services; and healthcare services for pregnant women. **Setting** The study is set in two communities in Eastern Ethiopia, one rural and one urban. **Participants** A random sample of 880 households residing in Kersa and Harar. **Results** Roughly 16% of households reported not having enough food to eat during the pandemic, an increase of 6% since before the pandemic. After adjusting for other variables, households were more likely to report food insecurity if they were living in an urban area, were a larger household, had a family member lose employment, reported an increase in food prices, or were food insecure before the pandemic. Households were less likely to report food insecurity if they were wealthier or had higher household income. **Discussion** After taking other characteristics into consideration, households in urban areas were at higher risk for food insecurity. These findings point to the need for expanding food assistance programs to more urban areas to help mitigate the impact of lockdowns on more vulnerable households.

1 **INTRODUCTION**

2 COVID-19 was associated with one of the largest disruptions to life in the 21st century. Beyond
3 immediate health effects,⁽¹⁾ the pandemic also had social and economic implications as government-
4 enforced lockdowns were implemented with the goal of mitigating the pace and severity of the
5 disease.⁽²⁾ To comply with these lockdowns, many businesses had to close in-person offices or
6 shops; for some, this meant closing permanently. Healthcare providers also had to restrict in-person
7 access to patients and/or decrease their services. These lockdowns are also thought to have affected
8 the health of children by limiting families’ ability to access food—especially in isolated regions of
9 resource-limited countries.⁽³⁻¹³⁾ Information on the extent to which households living in non-western
10 countries have experienced resource restrictions and other hardships remains limited due to
11 incomplete or nonexistent population health surveillance.⁽¹⁴⁾ We utilized data from an existing Health
12 and Demographic Surveillance System (HDSS) with catchment areas situated in an urban area of the
13 Harari People’s National Regional State and a rural area within the district of Kersa in Eastern
14 Ethiopia. We employed a social vulnerabilities framework^(15,16) that considered both social inequalities
15 and place inequalities as components of vulnerability to analyze food insecurity in the context of the
16 pandemic.

17

18 **BACKGROUND**

19 Food security is the condition in which “all people, at all times, have physical, social, and economic
20 access to sufficient, safe, and nutritious food that meets their dietary needs and food preferences for
21 an active and healthy life.”⁽¹⁷⁾ It has been described across four dimensions: food availability, food
22 accessibility, food utilization and food stability.⁽⁶⁾ It is anticipated that households around the world,
23 especially in resource-limited countries, have experienced increases in food *insecurity* due to the
24 social and economic repercussions of COVID-19.⁽³⁻¹³⁾ Pathways through which lockdowns may
25 exacerbate food insecurities include movement restrictions, food supply chain disruptions,
26 disruptions to informal markets, food price increases, reductions in individual or household income
27 due to job loss or business closure, and loss of access to government food programs.⁽⁷⁾ Although
28 mortality directly related to COVID-19 is lower among children and pregnant women compared to
29 older adults, reductions in access to basic nutrition, coupled with disruptions in access to
30 preventative maternal and child healthcare, may increase mortality and morbidity among young
31 children and pregnant women.^(4, 18-22) Particular concern has been raised regarding health
32 consequences of pandemic-related lockdowns in sub-Saharan Africa.⁽⁸⁾

33

34 **COVID-19 Lockdowns in Sub-Saharan Africa and Ethiopia**

35 In sub-Saharan Africa, national governments have taken substantial efforts to quell the spread of
36 COVID-19.^(2, 23) Implementation of physical distancing, sanitary measures, and encouragement of
37 personal responsibility have been used to help slow the spread of disease. In particular, communities
38 have been tasked with monitoring self-isolation measures, physical distancing, and quarantining. A
39 notable challenge that many sub-Saharan Africa countries have likely faced during pandemic-related
40 lockdowns is food insecurity.⁽³⁻⁹⁾ Many countries in Sub-Saharan Africa rely on food imports,
41 particularly in urban areas; lockdowns and related border closures may compromise these food
42 supply chains, leading to food shortages and price increases.⁽⁸⁾ Coupled with on-going climate
43 change, pests, and emerging crop diseases, it is anticipated that there will be many who are indirectly
44 hurt by the pandemic in addition to those directly affected by COVID-19. This is likely the case
45 Ethiopia, where the government responded with stringent measures to mitigate the pace and severity
46 of COVID-19.⁽²⁴⁾

47
48 Mitigation efforts in Ethiopia included establishing lockdowns, enforcing social distancing, and
49 placing emphasis on hygiene protocols; these efforts were initially adopted on March 16th of 2020,
50 tightened on March 20th, and a five-month state of emergency was declared on April 10th.⁽²⁴⁾ Yet,
51 social and economic disparities across different sociodemographic groups and geospatial
52 inequalities may have resulted in uneven implementation of these efforts.⁽¹¹⁾ Populations in urban
53 centers may have been better equipped to receive information about these directives compared to
54 rural populations that face communication barriers.⁽²⁵⁾ Rural populations likely confronted challenges
55 with implementing some measures due to limited access to handwashing facilities or lack spare
56 rooms in their dwellings for social distancing or quarantine; however lower population density may
57 have aided in social distancing between households.⁽²⁵⁾ Social and economic disparities may also
58 have resulted in differential vulnerability to adverse consequences of mitigation efforts.

59 60 **Vulnerability to Food Insecurity in Ethiopia**

61 Vulnerability, broadly defined, is the cumulative effect of cultural, economic, institutional, political,
62 and social processes that modify socioeconomic differences in the experience of and recovery from
63 hazards.^(15, 26) In the context of disasters, it is often not the hazard itself that creates the disaster;
64 rather, the disaster is the impact on individual and community coping patterns and the inputs and
65 outputs of social systems.⁽²⁷⁻²⁹⁾ Social vulnerability is partially the result of social disparities that shape
66 or influence the susceptibility of different groups to hazards while also controlling their capacity to
67 respond.^(15, 16) Factors often associated with vulnerability include demographic characteristics such

68 as age, ethnicity, race, and sex; socioeconomic status (e.g., income, wealth, employment, and/or
69 education); household composition (e.g., presence of children or elderly); and housing and
70 transportation.⁽³⁰⁾ However, social vulnerability also involves place disparities stemming from
71 characteristics of communities and the built environment that contribute to the vulnerability of place.
72 For example, differential availability of scarce resources between urban and rural areas may
73 exacerbate social vulnerabilities to hazards.^(16, 31, 32) To understand the broader consequences of the
74 pandemic, it is important to consider economic, political, and social markers of vulnerability at both
75 the individual and community level.⁽²³⁾

76
77 In Ethiopia, food insecurity was prevalent prior to the onset of the pandemic with those already
78 burdened by poverty at greater risk for experiencing food insecurity; it is anticipated that COVID-19
79 has exacerbated this vulnerability.^(7, 11) Households hit with an economic shock such as a job loss or
80 loss of income during the pandemic are likely at high risk for experiencing food insecurity, as they
81 must reduce expenditures to adapt to the economic shock.^(9, 33) Disadvantaged groups such as
82 women and children, people working in the informal sector or unemployed, those with limited financial
83 resources, those with medical conditions, and those relying on emergency food aid are also at high
84 risk.^(23, 34) Rural populations in Ethiopia are at elevated risk for food insecurity as climate change,
85 severe drought, conflict, and environmental degradation have culminated in societal shocks affecting
86 livelihoods, particularly for farmers.^(16, 35, 36) However, understanding geospatial differences in
87 vulnerability is complicated because international and national food programs were established to
88 provide food aid to needy populations, especially in rural areas, prior to the onset of the pandemic.⁽³⁷⁾
89 Given their strong emphasis on addressing food insecurity in rural areas, these programs may not
90 reach food insecure households living in urban areas.^(37, 38) Differential vulnerability requires targeted,
91 context specific interventions to address ancillary consequences of the pandemic such as increases
92 in food insecurity.⁽³⁹⁾ To help inform such interventions and increase their precision and efficacy, we
93 analyze demographic, economic, and social factors associated with food insecurity during the
94 pandemic.

95 96 **METHODS**

97 **Study setting**

98 The setting for this study is a predominantly rural area in the district of Kersa and an urban area in
99 the Harari People's National Regional State in Eastern Ethiopia.^(40, 41) The rural area consists of 24
100 kebeles (a neighborhood or ward representing the lowest level of local government), and covers 353
101 km² with a population of 135,754 in 25,653 households. The urban area consists of 12 kebeles, a

102 population of 55,773 in 14,768 households, across 25.4 km².⁽⁴¹⁾ The population has been followed
103 through a Health and Demographic Surveillance System since 2012, with demographic and health-
104 related information regularly collected (see Figure 1).
105

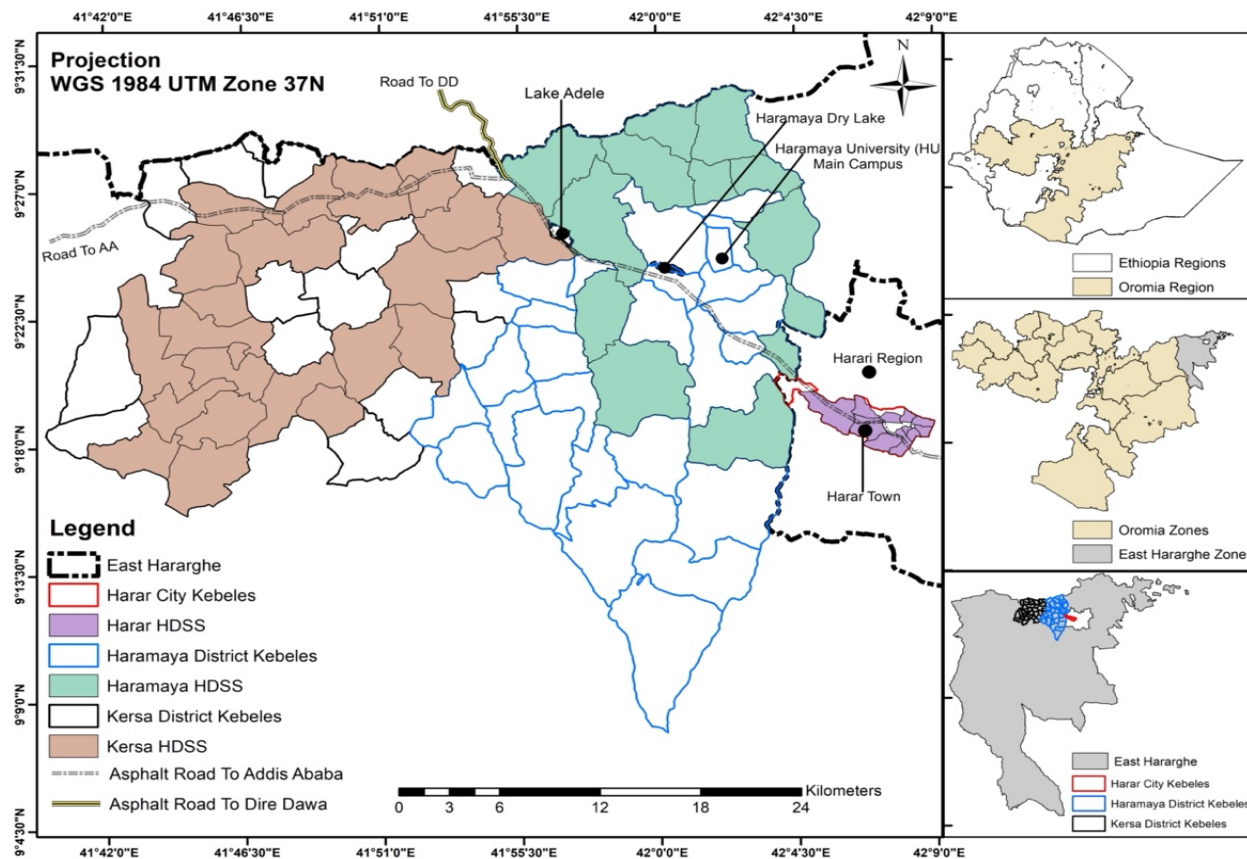

Figure 1. The Harar and Kersa Health and Demographic Surveillance Systems (HDSS) within East Hararghe, Oromia, Ethiopia. The smaller map panels on the right identify the location of the HDSS catchment areas within the East Hararghe Zone of the Oromia region in Ethiopia. The HDSS catchment in Haramaya (depicted in green) was in development during the data collection period, so households from this catchment were not included in this study.

112 Study design

113 This study is part of a broader investigation within the Child Health and Mortality Prevention
114 Surveillance (CHAMPS) network to understand the implications of COVID-19 lockdowns for child
115 health and mortality^(33, 42). We developed and administered a short quantitative instrument designed
116 to understand how the pandemic and related lockdowns may have affected livelihood, food
117 availability, and healthcare. Households were selected using simple random sampling. The sample
118 size was set to 440 each from the rural (Kersa) and urban (Harar) catchment areas (total sample size
119 of 880 households). The sample size was specified to detect prevalence of changes in accessing

120 care. A priori specifications were 50% of the population experiencing changes, 95% CI, precision of
121 0.05 and non-response adjustment of 10%.

122

123 The data collection instrument was organized into five sections: knowledge regarding the spread of
124 COVID-19; food availability; COVID-19 related shocks/coping; under-five child healthcare services;
125 and healthcare services for pregnant women. Questions in the survey instrument related to hardships
126 associated with the pandemic period asked respondents to consider whether they had experienced
127 hardships since March of 2020. Data were collected by HDSS enumerators in August and September
128 2021 through tablet-based in-person interviews with heads of households or their spouse.
129 Households' responses were linked with their data from the most recent HDSS round, which had
130 occurred in 2021, to incorporate information on age, sex, occupation, and education of the head of
131 household; the number of children under 5 years of age and the number of elderly adults (over 60
132 years) in the household; and household assets and residence construction materials.

133

134 Data quality assurance and cleaning followed standard operating procedures for the HDSS^(40, 43).
135 Inconsistent or missing data were flagged for data collectors to correct. Field supervisors and the
136 field coordinator selected a random sample of questionnaires for re-visits to verify the recorded
137 information. Implementation of the module was approved by the Institutional Health Research Ethics
138 Review Committee (IHRERC); approval reference number Ref.No.IHRERC/127/2021.

139

140 **Measures**

141 The variable of interest is *food insecurity*, indicating that a household reported not having enough
142 food to eat at any point since March 2020 based on responses to the question: “*Since the beginning*
143 *of the COVID lockdown, has it happened that your household did not have enough food to eat?*” The
144 variable is coded as 0 = no, 1 = yes. Additional variables identified the reasons that a household was
145 unable to get enough food, with respondents able to report multiple reasons: *couldn't afford to buy*
146 *more food; couldn't go out to buy food, afraid to go out to buy food; couldn't get groceries or meals*
147 *delivered; and stores did not have the food I wanted.*

148

149 Right-hand side variables were information on the head of household and characteristics of the
150 household and its homestead. Head of household variables were *age* (coded as 1 = less than 40
151 years, 2 = 41 to 44 years, 3 = 45 to 60 years, and 4 = sixty years and above); *sex* (coded as male = 0
152 and female = 1); *ethnicity* (coded as Amhara = 1 (reference) and other = 2, which included Oromo,
153 Somali, Gurage, Harari and Tigray); *education* (coded as no formal education = 0 (reference), any

154 level of education = 1); *occupation* (coded as 1 = farmer (reference), 2 = student, 3 = professional, 4
155 = sales, 5 = housewife, 6 = daily laborer, 7 = other employment, 8 = unemployed/retired). Household
156 variables were *urbanicity* (coded as urban (Harar) = 1 and rural (Kersa) = 0); *household size* (coded as
157 1 = 1-2 individuals (reference), 2 = 3-4 individuals, 3 = 5-6 individuals, 4 = 7-8 individuals, 5 = 9+
158 individuals); *children under 5* (coded as 0 = no, 1 = yes); *adults over age 60* (coded as 0 = no, 1 =
159 yes); monthly *income* (coded into quartiles as 1 = 0-1,200 Birr Ethiopia Birr (reference), 2 = 1,201-
160 2,000 Birr, 3 = 2,001-3,000 Birr, 4 = 3,001-4,600 Birr, and 5 = 4,600+)¹; *wealth index* based on a list
161 of household assets (coded as an 1 = poorest (reference), 2 = poorer, 3 = middle, 4 = richer, 5 =
162 richest)²; *job loss* by any household member since March of 2020 (coded as 0 = no, 1 = yes); *food*
163 *price increase* noticed by the household after March of 2020 (coded as 0 = no, 1 = yes); and *pre-*
164 *COVID food insecurity* (coded as 0 = no, 1 = yes)³.

165

166 **Analytic Strategy**

167 Data cleaning and analyses were performed using R version 4.2.0.⁽⁴⁴⁾ Education and occupation
168 related data were missing for nine household heads and observations for these households were
169 removed from analyses that included these variables. Data on pre-pandemic food insecurity was
170 missing for one household. There were no other missing values for the variables used.

171

172 Descriptive statistics were generated to assess the prevalence of food insecurity and other hardships
173 and sociodemographic characteristics. Pearson's Chi-square tests were used for preliminary
174 evaluation of associations between household characteristics and food insecurity. Unadjusted
175 logistic regression models were used to analyze associations with food insecurity (results available
176 upon request). Adjusted logistic regression was then used to control for other characteristics.

177

178 Several pathway-specific models were examined prior to fitting the final model and are available upon
179 request. The variables described above were selected for inclusion in the final adjusted logistic
180 regression because there was theoretical justification for association with food insecurity. We
181 assessed model fit with comparison of AIC and BIC scores—both scores were the smallest for the
182 fully adjusted model, indicating that this model had superior fit compared to simpler or pathway-

¹ Based on exchange rates at the time of the survey, this is roughly equivalent to 1 = 88+ USD (reference), 2 = 55 to 87 USD, 3 = 30 to 54 USD, and 4 = Less than 30 USD.

² For information on the principal components analysis used to compute the index, see Supplemental Materials.

³ Based on responses to the question: “Before mid-March 2020, did it ever happen that your household did not have enough food to eat?” from the CHAMPS Ethiopia Lockdown Module.

183 specific models. Results are reported as Adjusted Odds Ratios (AOR) with 95% confidence intervals
184 (95% CI) and visualized with forest plots.^(45, 46) Given anticipated differences in demographic,
185 economic, and social characteristics between households living in urban vs. rural areas, effect
186 modification was evaluated using interaction terms; however, the results of these analyses were not
187 statistically significant so they were not retained. Finally, a secondary analysis was conducted
188 wherein only those respondents who reported that their household had no difficulty obtaining
189 sufficient food prior to March of 2020 were included. This analysis examined factors associated with
190 the change from food secure prior to COVID-19 to food insecure during the pandemic. For this
191 analysis, some variables from the primary analysis such as ethnicity could not be included due to
192 lack of variation; other variables required recoding to due to sample size limitations.

193

194 **RESULTS**

195 A majority of households (63.3%) were headed by a male household member (Table 1). Average age
196 of the household head was 43 years with a standard deviation of 15. Oromo and Amhara were the
197 most common ethnicities, with 551 (62.6%) household heads identifying as Oromo and 222 (25.2%)
198 as Amhara. A majority (57.9%) of household heads had obtained at least some education; their most
199 common occupations were farmer (36.4%) and professional (18.3%). The majority of households
200 resided in urban areas (62.8%). The median number of household members was 5 with a standard
201 deviation of 2.4. Roughly a third of households reported having at least one child under the age of 5.
202 About a quarter of households had at least one adult family member over the age of 60. About 10%
203 of households reported that they were unable to obtain sufficient food prior to the onset of the
204 pandemic; a majority of these households (94%) continued to report food insecurity during the
205 pandemic.

206

207 Since the onset of the pandemic, 15.7% of households reported not having enough food to eat, an
208 increase of 5.8% from pre-pandemic levels; 59.5% of households reported an increase in food prices;
209 and 55.5% of households reported having at least one family member lose a job during this period.
210 Of the reasons reported by respondents for their household not being able to obtain sufficient food,
211 roughly 88% reported that they couldn't afford to buy more food, approximately 41% reported that
212 they couldn't get out to buy food, 23% of respondents reported fearing to go out and buy food, 20%
213 of respondents reported that they couldn't have groceries delivered, and 17% of respondents
214 reported that stores didn't have the food they wanted.

215 **Table 1: Descriptive Statistics and Chi-Square Values for HDSS Households**

		Household Food Insecurity				χ^2	p-value		
		Total	%	No	%			Yes	%

Data source: CHAMPS Ethiopia Lockdown Module data and CHAMPS Ethiopia Health and Demographic Surveillance data.

Notes: Nine observations were missing for head of household's education and occupation. One observation was missing for whether a household had experienced food insecurity prior to the onset of COVID-19. The "other" category for ethnicity included: Oromo, Somali, Gurage, Harari, Tigray, and "other". One observation was missing for whether a household had experienced food insecurity prior to the onset of COVID-19.

216
217
218
219
220
221
222

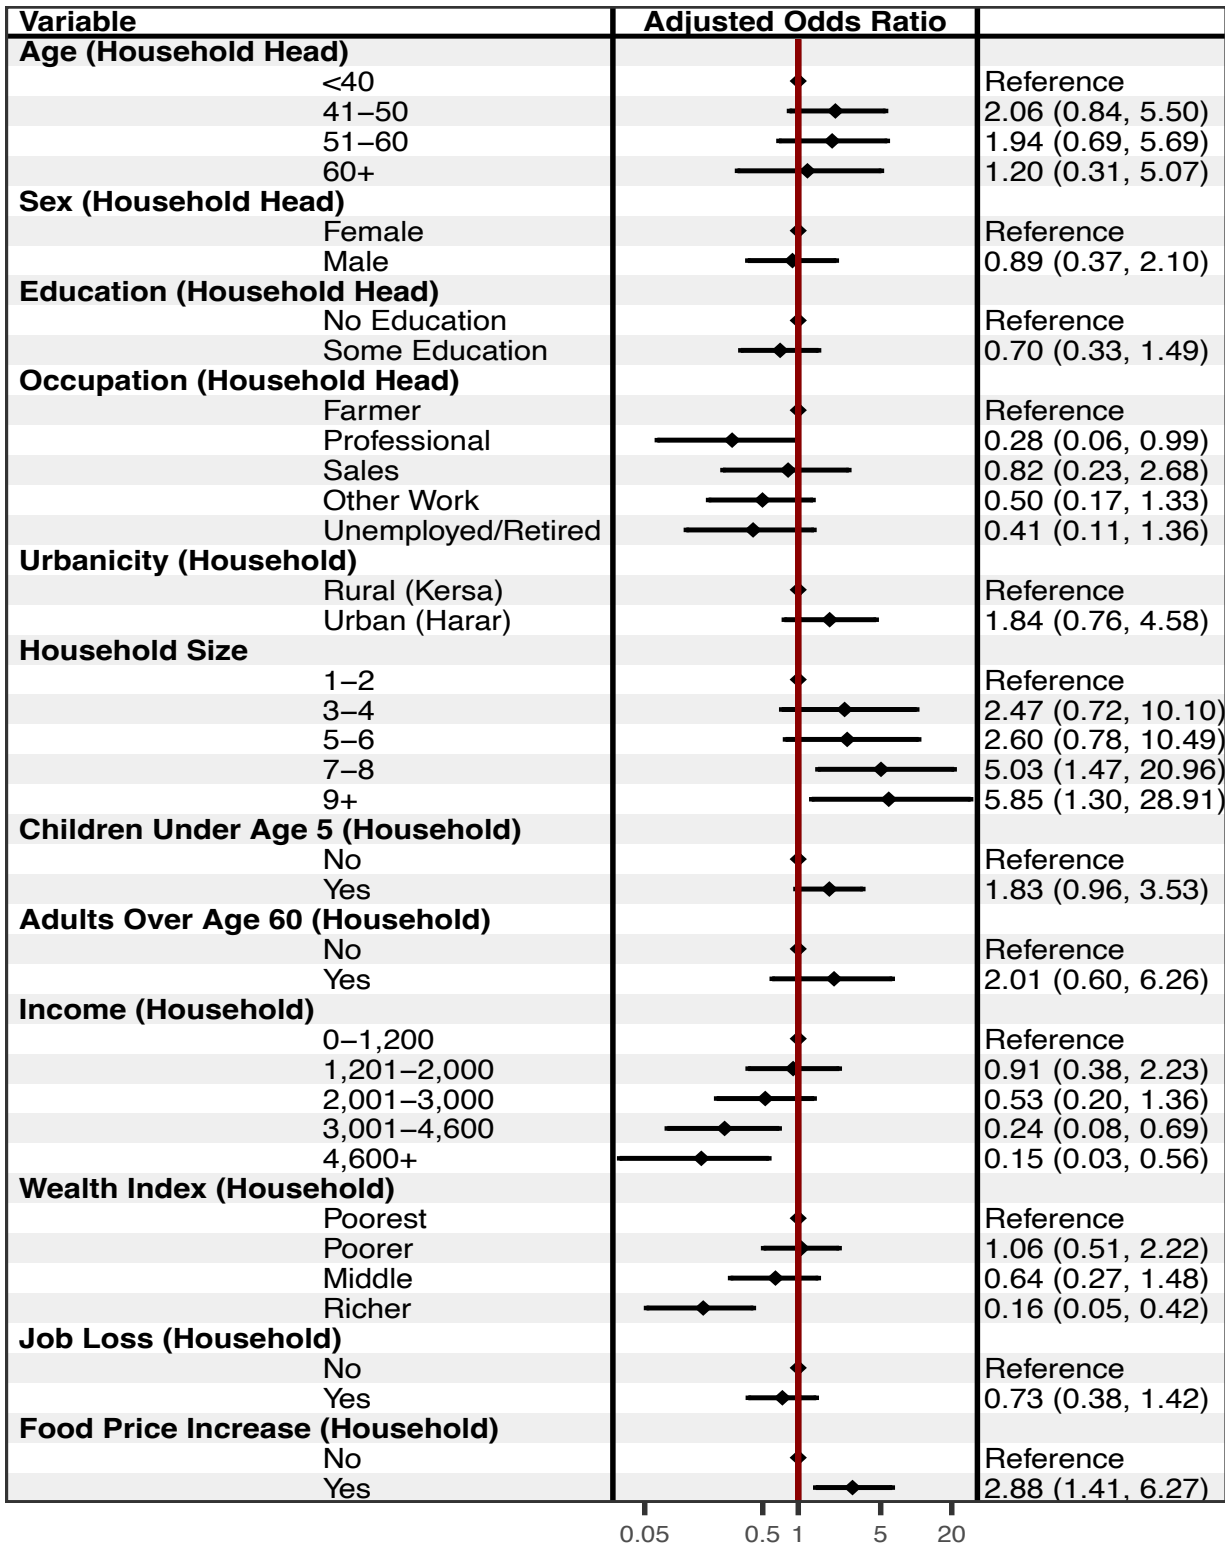

223 After adjusting for other characteristics (see Figure 2), households were more likely to report food
224 insecurity if the household head identified as an ethnic group other than the Amhara (AOR = 3.28,
225 95% CI [1.08, 12.05]) or if their residence was located in an urban compared to a rural area (AOR =
226 2.62, 95% CI [1.10, 6.46]). Compared to households with 1 to 2 household members, larger
227 households were more likely to have reported food insecurity; for example, for households with 7-8
228 members, the adjusted odds of reporting food insecurity were 5.42 times higher (95% CI [1.32,
229 23.35]). Compared to households with less than 1,200 Birr of monthly income, households with higher
230 income were less likely to report food insecurity; for example, AOR = 0.18 (95% CI [0.05, 0.57]) for
231 households with more than 4,600 Birr per month. Households in the wealthiest quintile were less
232 likely to report food insecurity compared to the poorest households, AOR = 0.18, 95% CI [0.05, 0.57]).
233 Households that observed increases in food prices were more likely to experience food insecurity
234 (AOR = 2.20, 95% CI [1.11, 4.53]). Finally, after adjusting for other characteristics, households that
235 reported food insecurity prior to the pandemic were more likely to report food insecurity during the
236 pandemic (AOR = 423.03, 95% CI [139.44, 1685.07]). Interaction terms for evaluating effect
237 modification between urban vs. rural residence and other characteristics were only statistically
238 significant for job loss during the pandemic—urban households that had had a job loss were most
239 likely to report insufficient food. All other associations were similar for urban and rural households.

240
241 In the secondary analysis that examined only those households that had indicated that they were
242 food secure prior to the onset of the pandemic (see Figure 3), larger households were more likely to
243 have reported food insecurity; for example, for households with 7-8 members, the adjusted odds of
244 reporting food insecurity were 5.03 times higher (95% CI [1.47, 20.96]). Compared to households
245 with less than 1,200 Birr of monthly income, households with higher income were less likely to report
246 food insecurity; for example, AOR = 0.15 (95% CI [0.03, 0.56]) for households with more than 4,600
247 Birr per month. Richer households were less likely to report food insecurity compared to the poorest
248 households, AOR = 0.16, 95% CI [0.05, 0.42]). Households that observed increases in food prices
249 were more likely to experience food insecurity (AOR = 2.88, 95% CI [1.41, 6.27]). Ethnicity was
250 dropped from the model due to lack of variation—only those households with a household head other
251 than the Amhara became food insecure during the pandemic. Similarly, no households from the
252 richest wealth quintile became food insecure during the pandemic.

262 **DISCUSSION**

263 In this study we examined the overall prevalence and the development of household food insecurity
264 during the pandemic in a rural and an urban community in eastern Ethiopia. Of the 10% of households
265 that reported having difficulty obtaining sufficient food prior to the onset of the pandemic, 94%
266 reported continued food insecurity during the pandemic. An additional 6% of households developed
267 food insecurity during the pandemic (these households reported having difficulty obtaining sufficient
268 food during the pandemic period, even though they did not have difficulties before). This level of
269 increase is somewhat lower than national level increases reported in other studies, but consistent
270 with findings that food insecurity increases were moderate in Oromia.⁽³⁸⁾ To contextualize this increase
271 in food insecurity, we note that at the time these data were collected there were 39,779 households
272 living within these communities. Applying the 6% increase to the entire population would correspond
273 to an additional 2,387 households reporting food insecurity during the pandemic. The primary reason
274 that households reported they were unable to obtain sufficient food was that it was too expensive.
275 Additional reasons reported by a number of households included the inability to go out and buy food
276 due to lockdown restrictions and fear to go out and buy food during the COVID-19 pandemic.

277
278 Overall, households were more likely to report experiencing food insecurity during the pandemic if
279 they were already food insecure prior to COVID-19. The pandemic degenerated the food security of
280 additional households that were vulnerable due to poverty or geospatial isolation; households were
281 more likely to report experiencing food insecurity if they resided in an urban vs. a rural area, had a
282 larger number of household members, had less monthly income, and were poorer compared to other
283 households in the community. The pattern of association for both monthly income and household
284 wealth is suggestive of a dose response to lower levels of household wealth and less monthly income.
285 These associations are consistent with risk factors reported in studies from resource limited
286 countries.^(6, 11-13) Shocks during the pandemic associated with increased risk of food insecurity
287 included increases in food prices and job loss; however, only increases in food prices were
288 associated with households reporting that they were unable to obtain sufficient food after adjusting
289 for pre-pandemic food insecurity.⁽⁶⁾ Interventions should anticipate that households experiencing
290 these shocks are at risk of food insecurity. Within the scope of the social vulnerability framework that
291 we employed, we found both household level characteristics as well as community level
292 characteristic associated with food insecurity; however, we found minimum between community
293 variation for the associations between household level characteristics and food insecurity, the
294 exception to these results is that the negative association between job loss and food insecurity was
295 amplified in urban areas.

296 One limitation of this study, common to studies using HDSS data, is that the findings reported here
297 are not generalizable outside of the communities under study.⁽¹⁴⁾ As an observational study, other
298 limitations include potential recall bias due to the extended length of time considered in the study or
299 unmeasured variable bias; for example, having data on household participation in Ethiopia's
300 Productive Safety Net Program (PSNP) may have helped contextualize our results, particularly the
301 relatively lower increase in food insecurity reported by households as other studies with access to
302 this information have noted that increases in food insecurity during the pandemic were more
303 moderate (less than 3%) for PSNP recipients.⁽³⁸⁾

304
305 An additional limitation is that, given the broader goal of understanding how households'
306 circumstances changed during the pandemic, our measure of food insecurity is less comprehensive
307 and does not adopt standard indices of food insecurity,⁽⁴⁷⁾ such as a household dietary diversity
308 score.⁽⁴⁸⁾ Implementing a more comprehensive measure may have improved our ability to identify
309 households that became food insecure during the pandemic in addition to the 6% that we have
310 reported on in this study. As a cross-sectional study, we cannot draw causal inferences. Given
311 findings from other studies that suggest hardships associated with COVID-19 lockdowns are
312 temporary,⁽⁷⁾ scholars should collect and analyze longitudinal data to evaluate changes in food
313 insecurity over time. In the context of demographic surveillance systems, follow-up data collection
314 using the same survey instrument is easy to attach to subsequent rounds of data collection already
315 being fielded. A concern common to studies involving complex humanitarian crises is that we are
316 unable to distinguish between the effects of the pandemic and possible impacts of the armed conflict
317 in the northern regions of Ethiopia that was temporarily contiguous with the pandemic.⁽⁴⁹⁾ However,
318 the political tension and civil conflict in Ethiopia have occurred primarily in the northernmost region
319 of Tigray, which is more than 400 km from the HDSS.

320
321 By identifying factors associated with households' inability to obtain sufficient food during the
322 pandemic period, our findings have policy implications. Established food assistance programs are
323 critical to support, even bolster, during pandemic periods as households previously identified as food
324 insecure will continue to require assistance. However, our findings suggest that after taking other
325 characteristics into consideration, households in urban areas were at higher risk for food insecurity.
326 These findings point to the need for flexibility in applying food assistance programs that may have
327 hitherto focused on assisting rural areas; intervention policies should consider the expansion of these
328 programs to more urban areas in the context of pandemics that cause major shocks to food supply
329 chains and other economic disruptions. Households in urban areas are particularly vulnerable to food

330 insecurity when economic shocks result in loss of employment for household members. Given these
331 findings, policies and practices that aim to mitigate the negative consequences of outbreaks should
332 consider supplemental economic assistance to provide aid to households hit by broader economic
333 shocks. These steps could mitigate the impact of lockdowns on more vulnerable households.

470 SUPPLEMENT A. WEALTH INDEX GENERATION

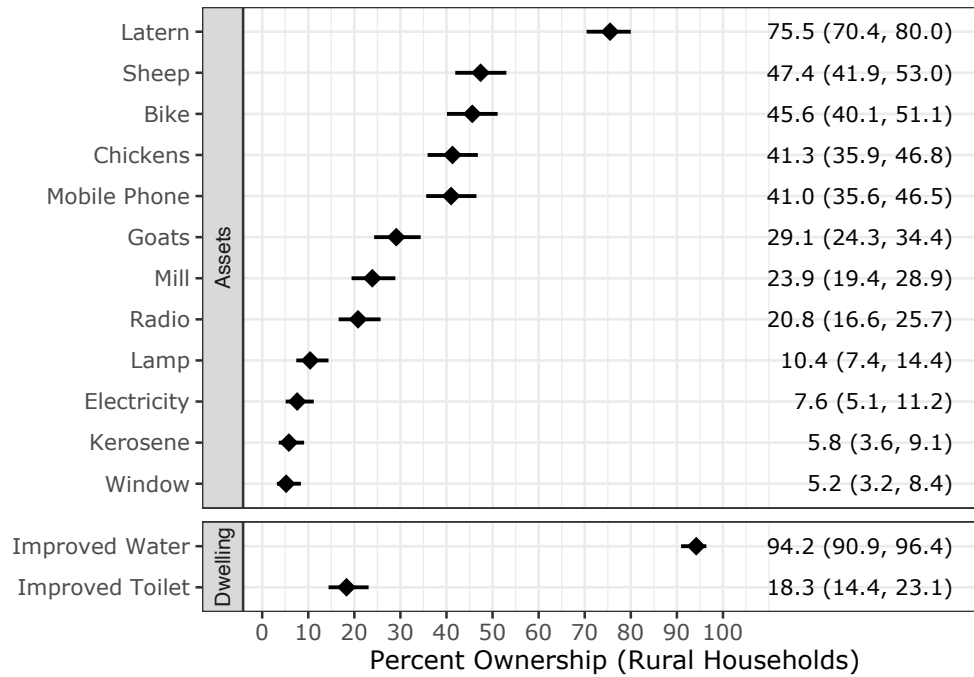

471 A wealth index was generated based on a collection of assets and construction materials for the main
472 dwelling of a given household. To generate the index, we followed recommendations from the DHS
473 and the World Food Programme (WFP) that summarize steps for calculating an asset based wealth
474 index,^(50, 51) including coding instructions for Stata,⁽⁵²⁾ and an adaptation of this coding process
475 implemented in R.^(31, 49) Using these documents to guide us, we generated our wealth index by
476 identifying a list of household assets for inclusion in our index computation, recoded all household
477 assets into dichotomous variables; recoded dwelling materials into improved vs. non-improved
478 dichotomous variables; divided our sample into rural and urban subsamples and assessed level of
479 representation of a given variable within the rural and urban subsamples (per WFP recommendations,
480 a given variable was included in further calculations if percent ownership ranged between 5 and 95
481 percent); employed principal components analysis with varimax rotation to calculate component
482 scores for those households living in either rural or urban areas, which explained 45% of the variation
483 in both subsamples; extracted and combined the PCA scores of the first component from the urban
484 and rural subsamples; and finally organized the scores into wealth quintiles to generate a composite
485 asset index. The resulting wealth quintiles are presented in Figure (4). The distribution of assets
486 owned by households as well as the materials used for constructing a household's residence are
487 presented as percentages in Figure (5).
