Abstract

RATIONALE: The number, size, and intensity of wildfires have increased in Canada, particularly in the western province of British Columbia (BC). Air pollution caused by wildfire smoke is linked to adverse health outcomes, especially for people living with asthma. Portable high-efficiency particulate air (HEPA) filters are effective at reducing indoor air concentrations of particulate matter associated with wildfire smoke. Using historical concentrations of particulate matter from wildfire smoke, we evaluated the cost-effectiveness of a government-sponsored HEPA air filter rebate program to improve asthma control and prevent exacerbations across Health Service Delivery Areas (HSDAs) in BC, Canada.

  METHODS: We developed a time-varying Markov model with health states for levels of asthma control, exacerbation severity (defined based on medication use, emergency department visits, and hospitalizations), and death. The analysis was performed from the healthcare payer perspective over a retrospective time horizon of 5 years (2018-2022). We obtained average daily concentrations of wildfire smoke-derived particulate matter of less than or equal to 2.5 microns in diameter ($PM_{2.5}$) for each HSDA from the Canadian Optimized Statistical Smoke Model. Clinical inputs were informed by the literature. We ran the model for the base case (full rebate and continuous year-round operation of air filters) and scenarios (variable rebate of \$100 [67% of purchase cost] and \$30 [20% of purchase cost] and either continuous or threshold-based operation of

---

air filters) in each HSDA in BC and calculated quality-adjusted life-years (QALYs) and costs. Incremental cost-effectiveness ratios (ICERs) were compared to a willingness-to-pay (WTP) threshold of $50,000/QALY.

RESULTS: In the base case analysis, HEPA air filter use resulted in increased costs of $82.84 (SE=1.05) and increased QALYs of 0.0012 (SE=0.0001) per person. Average ICER among BC HSDAs was $71,477/QALY (SE=3,378), with ICERs ranging from $38,628 to $85,445 per QALY in HSDAs. Across the province, the intervention was projected to prevent 4,536 exacerbations requiring systemic corticosteroids, 531 emergency department visits, and 458 hospitalizations during the 5-year time horizon. A full rebate was cost-effective in one of the 16 HSDAs across BC. The probability of cost-effectiveness ranged from 0.3% to 80.2% across HSDAs. A $100 rebate was cost-effective in all HSDAs except Northwest.

CONCLUSIONS: Our retrospective modelling suggests variable cost-effectiveness of portable HEPA air filters to reduce short-term asthma complications due to wildfire smoke, dependent on region and percentage of government rebate on the purchase cost of these filters. At the willingness-to-pay threshold of $50,000/QALY, rebates of up to two-thirds of the cost of filters were a cost-effective alternative across most of the geography of the province. However, it would be cost-effective for the BC government to provide a 100% rebate only in Kootenay Boundary.

Lay Summary

Wildfire smoke can increase flare up of symptoms among people living with asthma. These flare ups may require a visit to the emergency department or hospital admission. Research shows that portable HEPA air filters can significantly reduce concentrations of fine particles ($PM_{2.5}$, an important component of wildfire smoke) in homes and other buildings. Using air filters during smoke events is a common public health recommendation. However, air filters are not accessible to everyone, with units costing anywhere between $150 to a few hundred dollars. Does it make sense for the government of BC to offer a rebate on the cost of purchasing air filters for every person living with asthma in BC? In this study, we used historical data on wildfire smoke concentrations between 2018 to 2022, computer simulations, and health economics methods to answer this question. Our results suggest that it is likely cost-effective for the government to pay for a portion of the costs of air filters, particularly in the interior and northern interior parts of BC. We also looked at other scenarios, such as filter use only when outdoor pollution exceeds certain thresholds that typically trigger an air quality advisory. We found that a $100 rebate was cost-effective when the air filter was used continuously, whereas a $30 rebate was cost-effective when the air filter was turned on only during air quality advisories.

Background

The number, size, and intensity of wildfires in Canada have increased, particularly in the western province of British Columbia (BC) with the number of days with uncon-

trolled wildfire in BC expected to double or triple by 2100[1].

Wildfire smoke is composed of several pollutants, including fine particulate matter with diameters of 2.5 microns and smaller ($PM_{2.5}$). $PM_{2.5}$ and other air pollutants have been associated with increased respiratory symptoms, hospitalizations, and other adverse health effects in individuals with asthma [2].

People living with asthma are particularly susceptible to air pollution. Asthma exacerbations (also known as *flare-ups* or *acute severe asthma*) are episodes characterized by progressive worsening of cough, wheezing, shortness of breath and decrease in lung function [3]. Severe exacerbations can be fatal and can occur even in patients with well-controlled asthma [3]. Previous studies have shown that $PM_{2.5}$ from wildfire events can increase the risk of asthma exacerbations [4].

During wildfire smoke events, indoor $PM_{2.5}$ concentrations increase as smoke infiltrates into homes and other buildings. Because people typically spend >70% of their time in indoor environments, [5] indoor air quality is an important contributor to total air pollution exposure. Consequently, interventions that improve indoor air quality are important to protecting health, particularly during episodes of poor air quality, such as during wildfire smoke events. Portable high-efficiency particulate air (HEPA) filters can reduce indoor concentrations of $PM_{2.5}$[6]. These units work by drawing air across a highly efficient filter that traps particles, including $PM_{2.5}$, and release filtered air. HEPA and other filters can be portable, or be part of a buildings heating, ventilation, and air conditioning (HVAC) system, and often referred to induct filters.

As the climate emergency worsens and continues to impact air quality[7], there is growing consensus among the public health community that using air filters in indoor settings is an important health-protective intervention, particularly for vulnerable people. The Government of Canada currently provides tax benefits for the full cost of an air filter, cleaner, or purifier and up to $1000 for the purchase of an air conditioner for patients living with a chronic disease who have a prescription for these devices [8]. In 2021, the Canadian Government also announced a 25% tax credit for small businesses to upgrade their ventilation systems and purchase portable HEPA air filters [9]. In BC, the First Nations Health Authority (FNHA) provides portable air filters to communities affected by wildfires [10]. We are also aware of two similar programs in the US: an air filter distribution program for low-income asthma patients by the Bay Area Air Quality and Management District [11], and a HEPA filter loaner program by the Forest Stewards Guild in Santa Fe [12]. However, we are not aware of any formal analysis evaluating the cost-effectiveness of these programs from a health economics perspective.

In this study, we used a decision-analytic model to evaluate the cost-effectiveness of a government-sponsored portable HEPA air filters rebate program for improving asthma control and preventing asthma exacerbations caused by wildfire events in BC, Canada. Our analysis can serve as a blueprint for evaluating similar climate change adaptation strategies in BC and elsewhere.

Methods

We have reported the results of this study according to the recommendations and best practices set forth in the Consolidated Health Economic Evaluation Reporting Standards 2022 (CHEERS 2022) statement [13].

Our base case analysis assumes that the provincial government will offer a 100% rebate for portable HEPA air filters to all individuals diagnosed with asthma in BC. We used a retrospective time horizon of five years beginning in 2018 to the end of 2022, which was the most recent 5-year time horizon for which the data were available. This retrospective time horizon was necessary as daily projections of future wildfire $PM_{2.5}$ concentrations are not available. We assumed patients on average spent 69.6% of their time at home (and thus could benefit from the air filter for the proportion of time they were at home), based on the time use information collected in Statistics Canada's General Social Survey [5]. The target population was BC residents diagnosed with asthma with a starting age of 42 (the average age of BC residents)[14].

We projected costs in 2023 Canadian dollar and effects as Quality-Adjusted Life Years (QALYs) for patients with and without portable HEPA air filters in their homes, and report results for each Health Service Delivery Area (HSDA) in BC. We also report the number of averted cases of asthma exacerbations using model-projected exacerbation rates and crude asthma prevalence levels from April 1st, 2020 to March 31st, 2021 for each HSDA obtained from BCCDC[15]. We calculated Incremental Cost-effectiveness Ratios (ICER) and Net-Monetary Benefit (NMB) and reported cost-effectiveness at willingness-to-pay (WTP) threshold of $50,000/QALY.

The analysis was conducted from the healthcare payer perspective, with an annual discounting of 1.5% applied to costs and effects.

Stakeholder engagement

We developed a health economic analysis plan with early and ongoing input from stakeholders, including two patient partners living with asthma, two medical health officers, an environment health officer, and a policy analyst (see Acknowledgment section).

Model development

We developed a time-varying Markov model with seven health states corresponding to well-controlled asthma, partly-controlled asthma, and uncontrolled asthma (as defined per Global Initiative for Asthma (GINA) 2022 [3]) as well as exacerbations requiring either systemic corticosteroids (ExacSCS), a visit to the Emergency Department (ExacED), or hospitalization (ExacHosp), and death, respectively (Figure 1).

Background mortality was based on age-specific life tables for BC from Statistics Canada [16]. Mortality due to asthma exacerbations of each severity was based on a national review of asthma deaths in the UK [17, 18]. Annual transition probabilities

between asthma control states were based on an original analysis of Economic Burden of Asthma study where we calculated the proportion of transitions occurring between each control state over 5 visits conducted over 1 year of follow-up [19]. Rates of severe exacerbations leading to SCS, ED, or hospitalization were obtained from SYGMA II study[20]. We applied a risk ratio of 1.40 to individuals with partially controlled and uncontrolled asthma to reflect their higher probability of exacerbations. This parameter was based on an analysis of commercially insured patients in the US[21].

We ran the model using daily time cycles.

Figure 1: Markov health states and transitions

Air Pollution Exposure

Average daily outdoor $PM_{2.5}$ concentrations were obtained from CanOSSEM [22], a random forest machine learning model developed and validated by BC Center for Disease Control that projects retrospective average daily wildfire smoke levels for each postal code in BC. Outdoor $PM_{2.5}$ concentrations in HSDAs were obtained by linking postal codes to HSDAs using Postal Code Conversion File Plus (PCCF+) Version 7E[23]. Model assumptions are listed in Table 1.

Risk ratios for the effect of increased exposure to $PM_{2.5}$ on asthma outcomes, including salbutamol dispensation and asthma-related physician visit, ED visit, and hospitalizations were obtained from a recent meta-analysis[4] and a model validation study based on BC administrative health data [24].

Table 1: Model assumptions for evaluating cost-effectiveness of a portable air filter rebate program to prevent asthma exacerbations

Assumptions for base case analysis

HEPA air filters were assumed to operate continuously on their highest setting during model's time horizon.

We assumed that the government could offer rebates at a discount of 30% compared to the advertised retail price.

We assumed that HEPA filters will need to be replaced every 9 months of use based on the average manufacturer-recommended timeline, while the filtration unit will need to be replaced every five years regardless of how much it was used.

Residents were assumed to cover the cost of electricity and filter replacement.

We assumed that people living with asthma received one HEPA air filter unit each, even if there were multiple people with asthma in the same home. We assumed that air filters were placed in the main living space or main bedroom of the person with asthma.

We assumed people living with asthma spent the same proportion of their day at home as the general population.

Increased salbutamol dispensation (per canister) per 10 µg/m³ increase in $PM_{2.5}$ during wildfire events was used as a proxy for risk of worsened asthma control (ie. well controlled to partly controlled, or partly controlled to uncontrolled).

Potential additional benefits of HEPA air filters in reducing exposure to allergens, pathogens, and indoor sources of $PM_{2.5}$ such as cooking or wood stoves were not considered.

We assumed all patients would enter the "uncontrolled asthma" health state after an exacerbation event.

Historical wildfire-related $PM_{2.5}$ levels projected by the CanOSSEM model were assumed to be accurate.

Transition probabilities, utility and disutility values, rate ratios for the effect of increased $PM_{2.5}$ pollution on asthma outcomes, healthcare state costs, outdoor to indoor $PM_{2.5}$ infiltration rates, and HEPA filter efficiency rate were obtained from the literature (Table 2).

HEPA Air Filter Effectiveness

We chose what we considered to be a *typical* HEPA air filter unit with a clean air delivery rate (CADR) of 105 cfm for smoke, and a nominal air exchange rate of 4.8/hr for a coverage area of 15 m^2. Measured HEPA filter efficiency of 0.31 (defined as the ratio of indoor $PM_{2.5}$ measured throughout the year with HEPA to without HEPA filter) was obtained from a study led by one of our co-authors that evaluated air filter effectiveness in BC homes during smoke events [25] using a comparable air filter unit with a CADR of 150 cfm and nominal air exchange rate of 6/hr for a coverage area of 17.37 m^2 (Table 2). Varying filter effectiveness values of (±20%) were explored in one-way sensitivity analysis.

Costs

Costs included the initial purchase price of the HEPA air filter unit, background health-care costs based on asthma control level, and unit costs of exacerbations obtained from the literature. Unit costs and utilization were obtained from previous studies[26, 20].

Costs to patients for air filter operation such as electricity and replacement HEPA filters after every 9 months of use (based average replacement duration according to the manufacturer) were not included in the base case analysis, but are reported in scenario analysis.

Health State Utilities

Health state utilities were derived from the literature based on levels of asthma control, while severe exacerbations requiring systemic SCS, ED visit, or hospitalization were associated with a one-time disutility value derived from EQ-5D questionnaires [27].

Sensitivity Analyses

One-way deterministic sensitivity analysis was used to explore the effect of changing assumptions on the estimated costs and QALYs. Uncertainty in the results due to parameter uncertainty was explored through probabilistic sensitivity analysis with 1000 sampling from parameters distributions (Table 2) in each HSDA.

Our base case scenario assumed that the government covered the full cost of the air filter and that air filters were operating continuously throughout the five years of study. Here, we explore three different scenarios: 1) the government pays a $100 (67%) rebate, 2) the government pays a full (100%) rebate and air filters are turned on only when the outdoor pollution exceeds certain thresholds, and 3) the government pays a $30 (20%) rebate and the air filter operates only when outdoor $PM_{2.5}$ concentration is above a certain threshold. We chose rebate amounts based on convenience and existing provincial rebate programs (e.g. for energy efficient products [28]).

Software

Data preparation, model development, and statistical analysis was performed in R v4.2.3 using the *heemod* package v0.15.1 [29]. We used Quarto v1.3.326 to create a reproducible manuscript and used version control to keep track of methodological decisions and changes to the model.

Table 2: Model Parameters

Parameter	Base case	DSA	PSA	Source
Age at start	42	33|67		[14]

Mean infiltration efficiency without HEPA	61%		Normal (SD=0.27)	[25]
Mean infiltration efficiency with HEPA	19%		Normal (SD=0.20)	[25]
Filter Effect	31%	±20%	Beta	[25, 6]
RR for increased salbutamol dispensation per 10 μg/m³ increase in $PM_{2.5}$	1.04 [1.03-1.06]	1|1.20	Lognorma	[24]
RR for increased physician visit for asthma per 10 μg/m³ increase in $PM_{2.5}$	1.06 [1.04–1.08]	1|1.20	Lognorma	[24]
RR for asthma related ED visit per 10 μg/m³ increase in $PM_{2.5}$	1.07 [1.04–1.09]	1|1.20	Lognorma	[4]
RR for asthma related hospitalization per 10 μg/m³ increase in $PM_{2.5}$	1.06 (1.02–1.09)	1|1.20	Lognorma	[4]
Probabilities[1]				
Risk of death due to exacerbation (SCS)	0.0267%		Beta	[17, 18]
Risk of death due to exacerbation (ED)	0.1733%		Beta	[17, 18]
Risk of death due to exacerbation (hospitalization)	0.1801%		Beta	[17, 30]
Well-controlled to uncontrolled asthma, annually	14.52%		Beta	[19]
Well-controlled to partly-controlled, annually	81.28%		Beta	[19]
Partly-controlled to well-controlled, annually	72.03%		Beta	[19]
Partly-controlled to uncontrolled, annually	67.94%		Beta	[19]
Uncontrolled to partly controlled, annually	79.21%		Beta	[19]
Uncontrolled to well-controlled asthma, annually	38.34%		Beta	[19]
Annual rate of exacerbation (SCS) in controlled asthma	0.0845 p=8.05%[2]		Beta	[20, 21]

---

[1] Annual and monthly probabilities were converted rescaled to daily probabilities using $p_m = 1 - (1 - p)^{(1/n)}$

[2] Per Table 1 in Bateman et al. [20], 45.9% of patients had uncontrolled asthma, while 54.1% had controlled asthma. Per [20] the overall annual rate of exacerbations (SCS) was 0.1, which translates to an annual probability of 0.09516. We combined this information with risk ratios for asthma control level and exacerbations from [21] to solve for the annual exacerbation risks for those with controlled asthma:

Annual rate of exacerbation (ED) in controlled asthma	0.0084 p=0.84%		Beta	[20, 21]
Annual rate of exacerbation (hospitalization) in controlled asthma	0.0084 p=0.84%		Beta	[20, 21]
RR for exacerbations (SCS, ED, or hospitalization) in uncontrolled asthma vs. well-controlled	1.3977	±20%	Lognorma[21]	
RR for exacerbations in partly controlled asthma vs. well-controlled	0.9545	±20%	Lognorma[21]	
Exacerbation (SCS, ED, or hospitalization) to uncontrolled asthma	1-p_mortality		Fixed

1 USD (2018) = 1.6370 CAD (2023). Note: USD costs were converted to CAD using a currency exchange ratio of 1 USD = 1.365 CAD, and a consumer price index of 132.5 for February 2018 and 154.5 for February 2023.

Results

Average daily wildfire-related smoke concentration ranged from 2.5 μg/m^3 (2019-09-25, Northeast) to 410.6 μg/m^3 (2018-08-19, Kootenay Boundary). Significant year-to-year variability was observed among all HSDAs, with higher smoke concentration during years with more wildfire activity in the Interior and Northern Health regions as shown in Figure 2.

Base Case Cost-Effectiveness

Figure 3 shows the incremental cost-effectiveness ratio (ICER) for each HSDA in BC during the time horizon and the associated probability of cost-effectiveness when the uncertainty around model input parameters (Table 2) is taken into account. In the base case analysis in which government paid 100% of the purchase cost for HEPA filter units,

Figure 2: Smoke Exposure Levels (PM2.5) across BC

ICER was below a WTP threshold of $50,000/QALY in Kootenay Boundary and above the threshold elsewhere in the province.

Table 3 ranks HSDAs in BC in terms of HEPA rebate program cost-effectiveness, in descending order based on ICER. ICERs ranged from $38,628/QALY in Kootenay Boundary to $85,445/QALY in Northwest. Based on model projections and prevalence of asthma in BC, a total of 4,536 severe exacerbations leading to systemic corticosteroids use, 531 emergency department visits, and 458 cases of hospitalizations could be averted by continuous HEPA air filter use. Due to the larger populations and higher prevalence of asthma, the highest number of severe exacerbations averted (including systemic corticosteroids use, emergency department visits, and hospitalizations) were in Fraser South (968), Fraser North (649), Okanagan (611), and Vancouver (594).

Cost-effectiveness probabilities were highest in Kootenay Boundary (80.2%), Okanagan (43.6%), and Thomson Cariboo Shuswap (29.6%) HSDAs. One-way sensitivity analysis (Appendix) showed that costs and QALYs were most sensitive to the risk ratios of increased salbutamol dispensation and hospitalization per 10 µg/m³ increase in $PM_{2.5}$, utility of well-controlled and uncontrolled asthma, and the retail price of air filter units.

Table 3: ICERs for the portable HEPA air cleaner rebate program in BC

Scenario Analyses

Figure 4 shows results of scenario analyses. Our results suggest that a $100 rebate program would have been cost-effective at a WTP threshold of $50,000/QALY everywhere in the province except for the Northwest HSDA, in which the ICER was $50,800/QALY.

The next two scenarios are based on operation of HEPA filters when the outdoor $PM_{2.5}$ exceed a threshold concentration. We used a threshold of 25 μg/m^3 for $PM_{2.5}$, based on the BC government 24-hour ambient air quality objective which is used, along with other information to guide decisions on when to issue an air quality advisory [32].

Days with $PM_{2.5}$ concentrations above 25 μg/m^3 were most common in August, followed by September, July, October, and May. Our results suggest that a full purchase rebate along with operation of air filters on days in which outdoor $PM_{2.5}$ concentrations exceeded 25 μg/m^3 would not have been cost-effective anywhere in BC.

The last scenario considered a combination of a $30 rebate and operation of air filters on days in which $PM_{2.5}$ concentrations exceeded 25 μg/m^3. Our results suggest that the intervention would have been cost-effective in Kootenay Boundary, Okanagan, Thompson Cariboo Shuswap, and Northern Interior.

Operation Costs

While a formal evaluation of the intervention from a societal perspective is beyond the scope of this work, operation costs for patients were calculated to provide additional

(a) ICERs for the 100% HEPA rebate program   (b) Cost-effectiveness probability at WTP=$50,000/QALY

Figure 3: Base-case results

(a) Scenario 1, $100 rebate   (b) Scenario 2, Full rebate and air filters on when PM2.5≥25μg/m3   (c) Scenario 3, $30 rebate and air filters on when PM2.5≥25μg/m3

Figure 4: ICERs for HEPA Rebate Program - Different Scenarios

context. In the base case analysis when the air filter is operating continuously at its highest setting, patients anywhere in BC can expect to pay an average of $10 for 87.60 kWh of electricity and $40 for HEPA filter replacements annually, for a total of $50 per year. In the threshold-based scenarios, operation costs would be much lower (between $0.03 to $1.91) and across different HSDAs as shown in the Appendix Table 4.

Discussion

We found that across BC, offering a 100% rebate on HEPA air filters was cost-effective between 2018-2022 in Kootenay Boundary HSDA, which is the most wildfire prone HSDA in the province. Our results suggest that a $100 rebate program was cost-effective in most of the province when air filters were used continuously throughout the year. When air filters are only operated on days in which $PM_{2.5}$ levels exceed 25 µg/m^3, a $30 rebate program was also cost-effective in wildfire-prone areas of the interior and northern interior BC. To the best of our knowledge, this is the first cost-effectiveness analysis of a government-sponsored HEPA air filter rebate program designed to prevent wildfire smoke-related asthma exacerbations and improve asthma control.

Particulate matter pollution is a major cause of health and economic burden in Canada. In its 2022 report on the health of Canadians in a changing climate, Health Canada classified fine particulate matter among the three major outdoor pollutants which are collectively responsible for 15,300 premature deaths in Canada annually, with an economic cost of $114 billion [33].

There are growing calls for governments to better protect health, including by covering the cost of climate adaptation measures that protect the public. For example, the BC Coroner's report on the 2021 heat dome in BC, which resulted in 619 deaths, recommended that the BC government increase accessibility of air conditioners for use during extreme events by allowing them to be provided as medical devices through existing provincial programs [34]. Heat events and smoke can occur together and the current public health advice for the public is to create or access cool environments with clean air. Our results suggest that a similar program should be implemented for HEPA filter air cleaners to mitigate the impacts of extreme wildfire events in HSDAs with recurrently high wildfire smoke exposure.

We made several assumptions to develop our cost-effectiveness model. Where possible, we opted for assumptions that would minimize the chance of wrongly identifying the intervention as cost-effective. For instance, we narrowly focused on the short-term health benefits of HEPA filters in preventing acute asthma complications. However, chronic exposure to wildfire smoke may also be associated with increased risk of asthma incidence. Maintaining asthma control and preventing exacerbations is likely associated with improved long-term respiratory outcomes, which were not accounted for in our analysis. We only considered the benefits of air filters in reducing exposure to wildfire-related $PM_{2.5}$. However, HEPA air filters reduce concentrations of $PM_{2.5}$ from all sources, including traffic and industry, indoor sources, allergens, bacteria, and

respiratory viruses such as flu and COVID-19. We also assumed that HEPA air filter units would last only five years, regardless of how much they were in use, while the HEPA filters had to be replaced every 9 months.

In our base case analysis, we assumed the air filter to be turned on continuously for the 5-year time-horizon of the model, which is in line with Health Canada's guideline that asserts there is no threshold of exposure to $PM_{2.5}$ at which health effects may not occur[35]. Continuous operation of air filters also ensures further benefits from reducing exposure to indoor sources of $PM_{2.5}$, allergens, and reduced transmission of respiratory infections.

Our scenario analyses also showed that continuous operation of the HEPA air filter is more beneficial than turning it on and off daily based on the provincial 24-hour $PM_{2.5}$ ambient air quality objective. It makes sense for the continuous operation to be the most cost-effective choice from the government's perspective since there is more benefit to reap with no additional cost as the government is only paying for the upfront cost of a rebate.

Several limitations should be noted. First, the stochastic and hard-to-predict nature of wildfire events prevented us from conducting this analysis prospectively, as long-term prediction of wildfire events in BC with adequate spatial and temporal resolution are not available. Our retrospective results are still useful for future planning, as the frequency and intensity of wildfires in BC is expected to grow, and higher levels of exposure will make the intervention more cost-effective.

Second, retrospective wildfire-related $PM_{2.5}$ concentrations used in this study are based on the results of the CanOSSEM model, and thus subject to limitations and uncertainties of that model.

Third, within the observed $PM_{2.5}$ concentration range of 2.3 μg/m^3 to 417.3 μg/m^3, we have assumed a linear dose-response relationship for increased risk of change in asthma control and asthma exacerbations leading to either SCS, ED visit, or hospitalizations.

Lastly, due to a lack of data, we did not evaluate HEPA air filters in subgroups of the population based on sex, age, ethnicity, or social determinants of health, despite their established impact on the burden of the disease[36, 37, 38].

Conclusion

Between 2018 and 2022, offering a 100% rebate on portable HEPA air filters was a cost-effective intervention to reduce short-term asthma complications due to wildfire smoke in Kootenay Boundary but not in other HSDAs in BC. Consumer rebates of up to $100 (about two-thirds of the cost of the air filter unit) were a cost-effective alternative in most of the province, especially the interior and northern interior parts of the province where wildfire exposure is higher.

Acknowledgments

We would like to acknowledge that most of the activities of this research project were conducted on the traditional, ancestral, and unceded territory of the Musqueam people. We would like to thank our patient partners for sharing their feedback and insights with us throughout this study. We are also thankful to our knowledge user advisers Dr. Michael Schwandt (Medical Health Officer, Vancouver Coastal Health), Dr. Silvina Mema (Medical Health Officer, Interior Health), Paula Tait (Health & Resource Development Technical Adviser at Northern Health), and Jade Yehia (Environmental Health Policy Lead at BC Ministry of Health). We would like to express our gratitude Dr. Mohsen Sadatsafavi (University of British Columbia) and Dr. Zafar Zafari (University of Maryland) for their help with health economics methods. Lastly, we are very thankful to Dr. Sarah Henderson and Naman Paul (BC Centre for Disease Control) for sharing results of the CanOSSEM model with us. This study was funded by Legacy for Airway Health.

Appendix: Operation Costs

Table 4: Average annual operation cost for patients under different scenarios

HSDA	Base case, Scenario 1	Scenarios 2 and 3
Central Vancouver Island	$50.00	$0.36
East Kootenay	$50.00	$1.61
Fraser East	$50.00	$0.70
Fraser North	$50.00	$0.61
Fraser South	$50.00	$0.55
Kootenay Boundary	$50.00	$1.91
North Shore/Coast Garibaldi	$50.00	$0.36
North Vancouver Island	$50.00	$0.25
Northeast	$50.00	$1.13
Northern Interior	$50.00	$1.20
Northwest	$50.00	$0.03
Okanagan	$50.00	$1.83
Richmond	$50.00	$0.36
South Vancouver Island	$50.00	$0.36
Thompson Cariboo Shuswap	$50.00	$1.66
Vancouver	$50.00	$0.36

Appendix: Deterministic Sensitivity Analysis
