Take-home message

Severe SARS-CoV-2 pneumonia, typically presented with hypertension as the most
common comorbid factor, fever as the most common symptom, and acute respiratory
distress syndrome as the most common complication, has lower lymphocytes count
(CD8+ and CD4+ T cells) and higher levels of D-dimer, lactate dehydrogenase and
cytokines. Older age, comorbidities, laboratory findings might be the predisposing
factors of disease severity.

Abstract

Purpose: Severe SARS-CoV-2 pneumonia remains incompletely understood. We

aimed to summarize current evidence regarding clinical features, laboratory

findings, and treatment of severe pneumonia.

Methods: Online databases were searched from December 1, 2019, to April 15, 2020 related to SARS-CoV-2. The titles and abstracts in English or Chinese for articles were screened. Studies containing more than 10 adult patients with severe pneumonia and presenting data on clinical features and laboratory findings were selected and extracted independently by two reviewers.

Results: We identified a total of 13 articles including one from Italy representing the majority of cases, and the remainder from China. Over the 2,129 severe pneumonia in these 13 articles, the mean ages ranged from 49 to 64 years. Patients typically presented with hypertension as the most common comorbid factor, fever as the most common symptom, and acute respiratory distress syndrome as the most common complication. As compared to non-severe pneumonia, severe pneumonia featured lower counts of lymphocytes, CD8+ and CD4+ T cells, and higher levels of D-dimer, lactate dehydrogenase, IL-6 and IL-10. There is a lack of evidence for using antivirals, and a debate on using corticosteroids in treatment.

Conclusions: This is the first systematic summarization of the aspects of severe pneumonia. Older age, comorbidities, laboratory findings might be the predisposing factors of disease severity. Multicenter- and large population-designed studies, with confounding controlled and long enough to accommodate follow-ups, are urgently required to provide the guidance to disease management.

Keywords: severe SARS-CoV-2 pneumonia; scoping review; clinical characteristics; laboratory findings; treatment.

Introduction

Outbreak of a novel coronavirus disease, COVID-19, initiated in Wuhan, China in December of 2019. This disease is caused by the severe acute respiratory syndrome coronavirus 2, SARS-CoV-2. Coronaviruses are a large family of viruses that cause illnesses ranging from the common cold to more severe diseases such as Middle East Respiratory Syndrome (MERS) and Severe Acute Respiratory Syndrome (SARS). These diseases are primarily transmitted by respiratory droplets and close personal contact [1]. As of June 4, 2020, there were 6,475,644 laboratory-confirmed cases have been reported, including 386,544 deaths globally [2].

Cases with severe SARS-CoV-2 pneumonia (Referred to as severe pneumonia) possessed the high case-fatality [3, 4] and required intense attention [5] according to previous studies. A complete understanding of severe pneumonia should facilitate faster diagnosis and more effective treatment. Unfortunately, information about the characteristics and treatments of severe pneumonia is limited, heterogeneous, and not consistently defined. This scoping review aimed to summarize current evidence regarding the demographics, comorbidities, clinical manifestations, laboratory findings, therapies, and outcomes of severe pneumonia.

Methods

The protocol for this scoping review is provided in the supplementary materials. The review was conducted according to the framework described by Arksey and O'Malley [6], and was in accordance with the Preferred Reporting

Items for Systematic Reviews and Meta-Analyses extension for scoping reviews (PRISMA-ScR) statement [7]. After identifying relevant studies that met the selection and inclusion criteria, data was examined and tabulated. Findings from this data were used to draw conclusions according to our research aims. All findings and statements regarding the severe pneumonia in this scoping review were based on the information from the included studies.

Identifying relevant studies

To include the maximum number of relevant articles pertaining to severe pneumonia, we searched for the terms "2019 novel coronavirus", "2019-nCoV", "Coronavirus disease 2019 virus", "COVID-19 virus", "SARS-CoV-2" and "SARS2". These terms were searched in the title and/or abstract field of literature published between December 1, 2019 and April 15, 2020 in PubMed, Medline, Embase, Web of Science, preprint servers for health sciences (MedRxiv and BioRxiv), Cochrane library and China National Knowledge Infrastructure databases. Duplicates were removed using EndNote X8 software. We did not set a language restriction in the process of literature search, the final search strategy for PubMed can be found in the supplementary methods. We manually reviewed titles and abstracts in English or Chinese, regardless of the language of the publication. For publications in languages beyond English and Chinese, none were proceeded for full-text screening after reviewing the publications' abstract.

Study selection and inclusion criteria

Potential articles were reviewed to ensure that they presented clinical features or laboratory findings of patients with severe pneumonia. Two authors

(X.L. and H.Z.) independently examined the titles, abstracts, and full texts of publications to determine if they would be included in the study. Disagreement was resolved either through discussion with each other, or with a third researcher (Z.C.) vote if necessary. The inclusion criteria contained: (1) Adult patients with laboratory-confirmed SARS-CoV-2 pneumonia: positive result of real- time reverse transcriptase–polymerase chain reaction (RT-PCR) assay of nasal or pharyngeal swabs; (2) Severe pneumonia with at least one of the following: i) respiratory rate $\geq$ 30 breaths/min, ii) SpO_2 $\leq$ 93% on room air, iii) PaO_2/FiO_2 $\leq$ 300 mmHg [8]; (3) More than 10 patients with severe pneumonia included in the study; (4) Any clinical and/or laboratory data presented. The PaO_2/FiO_2 in acute respiratory distress syndrome (ARDS) is at least less than 300 mmHg based on the Berlin definition [9]. Any type of study design such as single center- or multicenter-based, small or large sample size-based, retrospective or prospective, observational, and randomized controlled trial (RCT), would be selected if the study met the inclusion criteria.

Data charting and quality assessment

The charted information included the name of the first author, study institution, study type, definition of severe pneumonia, case number, gender, age, comorbidities, symptoms, complications, laboratory findings, treatment, prognosis, and the comparison between severe and non-severe pneumonia when appropriate. Some data about cytokines and lymphocyte subsets were extracted from graphs with software GetData Graph Digitizer (version 2.26). Data was inputted into an excel spreadsheet with all data charted first independently

by two authors (X.L. and H.Z.) and then compared. Disagreement on charted

information was resolved either through a discussion between each other, or with

a third researcher (Z.C.) vote if necessary.

With the Joanna Briggs Institute (JBI) critical appraisal tool for case series,

or cross-sectional studies if comparing severe and non-severe pneumonia [10],

two researchers (X.L. and H.Z.) independently assessed the methodological

quality of individual study and determined the extent to which the study has

addressed the possibility of bias in its design, conduct and analysis. The overall

appraisal on each source of evidence was decided to include or exclude the

study. Disagreement on quality assessment was resolved either through a

discussion between each other, or with a third researcher (Z.C.) vote if necessary.

Summarizing the findings

Articles were classified into one of the following research domains:

demographics, comorbidities, clinical manifestations, complications, laboratory

findings that including routine tests, cytokines and counts of lymphocyte subsets,

treatments, and prognosis. We counted the number of studies included and

summarized the findings. We calculated overall ratio of each item in

comorbidities, symptoms and complications, and narratively described overall

ratio with the range of lowest and highest values amongst the related studies.

Categorical data were expressed as numbers (%). Continuous data were

expressed as medians and interquartile ranges (IQR) or means and standard

deviations. The significant differences between severe and non-severe

pneumonia were recorded if appropriate.

Results

The literature search identified 4,824 articles. After discarding 1,883

duplicates, the titles and abstracts of 2,941 articles were screened. Sixty-three

articles were retrieved for full-text evaluation. Of these, 50 articles were excluded

for the following reasons: the study did not define severe pneumonia (n=25);

clinical or laboratory data were unavailable (n=13); the study possessed less

than 10 severe pneumonia (n=12). Thirteen studies (12 in English, one in

Chinese [11]) with 2,129 cases of severe pneumonia meeting our inclusion

criteria were included [3, 11-22], one from Italy with by far the majority of the

severe pneumonia; and the remainder from China (Figure 1).

Severe pneumonia was defined according to the World Health

Organization (WHO) guideline in 12 studies [3, 11-21]. The Italian study

confirmed all patients as having severe pneumonia after contacting the author

[22].

Eleven studies contained both severe and non-severe pneumonia [3, 11-

20], while the remaining two studies exclusively included severe pneumonia [21,

22]. Most studies were retrospective, observational, and single-center-based [3,

11, 13-18, 20]. Most studies summarized both clinical characteristics and

laboratory findings [3, 12-15, 17-21]. Two studies without available clinical data

described information regarding features about cytokines and lymphocyte

subsets [11, 16] (Table 1).

Sources of evidence appraisal

The quality assessment of individual sources of evidence by JBI tool was

summarized for both case-series and cross-sectional studies. All studies had

good quality and were processed for data summarization (Table S1-2).

Demographics

All studies used in this review included demographics of patients with

severe pneumonia [3, 11-22]. The percentages of male severe pneumonia

patients ranged from 52.4% to 90.9% but no study claimed that male patients

were at greater risk of developing SARS-CoV-2 pneumonia. The mean age of

patients in each study ranged from 49 to 64 years old.

Comorbidities

Eleven studies selected for review described comorbidities of severe

pneumonia [3, 12-15, 17-22]. The most frequent comorbidity was hypertension

(45.0% (8.0-48.8% by 10 studies) [3, 12-15, 17-20, 22], followed by diabetes

(16.7% (7.7-30.8%) by 11 studies) [3, 12-15, 17-22], cardiovascular disease

(17.1% (4.0-23.1%) by nine studies) [3, 12, 14, 17-22], and chronic pulmonary

disease (4.5% (2.5-17.6%) by eight studies) [3, 12, 14, 17-20, 22]. Chronic

kidney disease (3.8% (1.3-15.1%) by four studies) [14, 17, 20, 22],

cerebrovascular disease (11.3% by one study) [14], and cancer (6.5% (0-7.8%)

by six study) [3, 15, 18, 20-22] were also found in the patients with severe

pneumonia (Table S3).

Clinical manifestations

Nine of the selected studies described symptoms present in patients with

severe pneumonia [3, 12-15, 17-20]. On admission, the most common symptom

was fever (90.6% (79.2-100%) by nine studies) [3, 12-15, 17-20]. Additional

common signs included cough (73.8% (56.8-96.0%) by nine studies) [3, 12-15,

17-20], fatigue (50.9% (47.5-100%) by eight studies) [3, 12-15, 17, 18, 20] and

dyspnea (34.6% (0-100%) by eight studies) [3, 12, 13, 15, 17-20], only one study

reported no dyspnea at admission in severe pneumonia [15]. Sputum production,

headache and digestive symptoms were also reported. Less commonly recorded

symptoms were myalgia, pharyngalgia, chest tightness, dizziness and anorexia

(Table S4). As compared to non-severe pneumonia, severe pneumonia were

more frequently featured with dyspnea [3, 12, 13, 19], cough [17, 19], sputum

production [12, 15, 19], fatigue [14, 18], and nausea [17]. No difference of fever

prevalence was found at admission.

Complications

Four studies described complications regarding severe pneumonia [3, 13,

14, 18]. ARDS (79.5% (50.0-100%) by four studies) was the most common

complication in severe pneumonia [3, 13, 14, 18]. Other fatal complications

included acute cardiac injury (10.9% (5.0-30.8%) by three studies) [3, 13, 18],

acute kidney injury (7.8% (2.5-23.1%) by three studies) [3, 13, 18] and shock (7.5%

(2.5-23.1%) by two studies) [3, 18]. Additionally, liver dysfunction and

disseminated intravascular coagulation were also reported [13] (Table S5).

Laboratory findings

Of the 10 studies describing laboratory findings for severe pneumonia [3,

12-15, 17-21], nine of them including a comparison between severe and non-

severe pneumonia [3, 12-15, 17-20]. We synthesized medians for white blood

cell (WBC) count (4.5-11.3×10^9/L by 10 studies) [3, 12-15, 17-21], neutrophil

count (2.8-10.6×10^9/L by seven studies) [3, 12-15, 18, 19], lymphocyte count

(0.4-0.9×10^9/L by 10 studies) [3, 12-15, 17-21], and lactate dehydrogenase (LDH)

(264.0-567.2 U/L by seven studies) [3, 13-15, 18, 20, 21]. When compared with

non-severe pneumonia, severe pneumonia had the lower lymphocyte count [3,

12-15, 17-20], higher levels of D-dimer [3, 13-15, 17, 18, 20], LDH [3, 13-15, 18,

20] and hypersensitive troponin I [3, 20] in all associated studies. Severe

pneumonia presented with the higher levels of WBC [3, 13-15, 17], neutrophil [3,

12-15, 18], ALT [3, 13, 15], AST [13, 15, 18] and C-reactive protein [13-15, 17-

20], and lower albumin levels [3, 13, 18, 20] in the majority of related studies. The

levels of platelet count, hemoglobin, prothrombin time, activated partial

thromboplastin time, creatine kinase and creatine did not significantly differ

between severe and non-severe pneumonia (Table S6).

Six studies reported levels of cytokines [3, 11, 13, 15, 16, 20], and four

studies reported counts of lymphocyte subsets for severe pneumonia [13, 15, 16,

20]. We synthesized medians for IL-6 (7.1-73.8 pg/mL) [3, 11, 13, 15, 16, 20], IL-

10 (4.6-11.1 pg/mL) [3, 11, 13, 15, 16, 20], CD8+ T cell (124.3-179.0×10^6/L) [13,

15, 18, 20] and CD4+ T cell (171.5-275.7×10^6/L) [13, 15, 18, 20]. As compared to

non-severe pneumonia, severe pneumonia in most studies had higher levels of

IL-6 [11, 15, 18] and IL-10 [3, 13, 15, 18], and lower CD8+ [13, 15, 18, 20] and

CD4+ T [13, 18, 20] cell counts. The medians of TNF-alpha, B and NK cell count

were not significantly different between severe and non-severe pneumonia

(Table S7).

Treatment

Eight studies described treatment for severe SARS-CoV-2 pneumonia [3,

12-14, 18, 20-22]. Antiviral therapy was commonly used for severe pneumonia

(48.2-100% by six studies) [3, 12, 14, 18, 20, 21]. The most frequently used

antiviral agent was oseltamivir (75 mg twice daily, orally), other antivirals used

included lopinavir, ritonavir, remdesivir, favipiravir, and darunavir-cobicistat.

Corticosteroid was widely used in China (33.7-93.2% by six studies) [3, 13, 14,

18, 20, 21], but was not reported as used in Italian study [22]. Other used

treatments included immunoglobulin (54.7-66.2%) [14, 20], antibiotic agents

(43.2-100%) [3, 12-14, 18, 20, 21], renal replacement therapy (4.5-23.1%) [3, 18,

21], and oxygen support (nasal cannula (0.8-29.4%) [3, 12, 22], non-invasive

ventilation or high flow nasal cannula (8.6-81.8%) [3, 12-14, 18, 21, 22], invasive

mechanial ventilation (2.5-72.3%) [3, 12, 18, 20-22] and extracorporeal

membrane oxygenation (0-15.3%) [3, 18, 20-22]). Ventilation therapy, especially

mechanical ventilation, was the primary treatment for ARDS. The Italian study

presented details reporting the positive end-expiratory pressure (PEEP) median

was 14 cm H_2O, and PEEP levels as high as 22 cm H_2O were applied. When

compared with younger patients (≤63 years), older patients had higher FiO_2 and

lower median PaO_2/FIO_2. No difference of PEEP was reported [22].

The therapeutic efficacy was evaluated or reported in three studies [14, 21,

23], Cao et al. reported no benefit was observed with lopinavir-ritonavir treatment

beyond standard care [21], no benefit was found for survival probability when

using ribavirin, oseltamivir, arbidol, corticosteroid, or immunoglobulin [14, 23]

(Table 2).

Prognosis

The case-fatality rates for severe pneumonia varied from 15.4% to 49.1%

in six studies with one to four weeks follow-up [3, 13-15, 21, 22].

Discussion

This scoping review, the first systematic summarization of aspects from

2,129 patients of severe pneumonia in 13 studies, provided urgently needed

information to frontline clinicians and allied health professionals involved in the

care of severe pneumonia, and identified the knowledge gaps between what

already known and unknown.

As for the management of severe pneumonia, there have been clinical

guidelines released by WHO [8] and Surviving Sepsis Campaign (SSC) [24, 25].

However, the guidelines do not give any recommendation on the predisposing

factors of disease severity or mortality in patients with severe pneumonia. In

published literatures, studies on COVID-19 suggested old age and comorbidities

as the predisposing factors of mortality [26, 27], but not exclusively observed in

severe pneumonia. A retrospective cohort study, with the confounding

adequately adjusted, found older age as a predictor of poor prognosis in 191

adult patients with COVID-19 [26]. Another study based on 150 patients of

COVID-19, with the limitation such as unadjusted confounding in methodology,

indicated cardiovascular disease as the clinical predictor of mortality [27]. In this

scoping review, the older age and higher frequency of comorbidities such as

chronic pulmonary disease, hypertension or diabetes in severe pneumonia

compared to non-severe pneumonia might serve as the potential predisposing

factors of disease severity, but reported with unadjusted estimates [14, 15, 17-

20]. So, multicenter- and large population-designed studies, with careful

delineation of disease severity (consistent definition, enough monitoring time),

survivor or non-survivor categorization, and confounding adequately controlled,

are required to define the predisposing factors that contribute to disease severity

and mortality in severe pneumonia.

No recommendation on using laboratory examinations to predict disease

severity or mortality in patients with severe pneumonia was given based on the

guidelines. Current evidence from studies of patients with COVID-19 revealed

lymphopenia as the predisposing factor of disease mortality [27, 28], and

considered D-dimer as the risk factor of complications such as thrombosis [29]

and septic shock [4, 26, 27]. In this review, the summarization of laboratory tests

also might have some suggestions on the predisposing factors of disease

severity. For example, the consistent existing of lymphopenia and increase of D-

dimer and LDH in severe pneumonia across all studies suggests lymphopenia,

D-dimer and LDH as the potential critical factors of disease severity, but needs

validation from confounding-controlled study. The higher levels of IL-6 and IL-10

whereas lower counts of CD8+ and CD4+ T cells, due to the cytokine storm and

exhausted immunity in severe pneumonia, also might be used for disease

severity prediction [3, 30]. No evidence on utilizing laboratory tests for mortality

or complication prediction in severe pneumonia according to this scoping review.

Recommendations regarding therapies for severe pneumonia have been

listed by the guidelines [8, 24, 25]. Guidelines suggest against the routine use of

antiviral agents in severe pneumonia treatment, as no study reported antivirals

had a direct inhibitory effect in SARS-CoV-2 virus replication [31, 32] or provided

clinical benefit in COVID-19 patients in randomized controlled trials (RCT) [21,

33]. An open-label RCT with 199 patients did not observe a benefit from

lopinavir-ritonavir treatment beyond standard care [21]. Another recent

multicenter-based RCT found remdesivir was not associated with statistically

significant clinical benefits in severe pneumonia [33]. Our scoping review also

does not support the routine use of antivirals due to the lack of observed efficacy

from empirically using antivirals at the beginning of pandemic. Therefore, we are

expecting other ongoing RCT to confirm or exclude a benefit from antivirals for

severe pneumonia. The routine use of corticosteroid is not recommended in

COVID-19 treatment by the guidelines [8, 24, 25], due to the lack of effectiveness

and possible harm such as delayed viral clearance based on the experience of

using corticosteroids for SARS [1] and MERS treatment [34, 35]. However,

Chinese clinicians thought the unrecommended use of corticosteroid was mostly

based on the findings from observational and inconclusive studies, which they

thought should not be a reason for abandoning corticosteroid use in COVID-19

[36, 37]. A recent study result from University of Oxford, but have not been

published or subjected to scientific scrutiny, showed low dose of dexamethasone

(6 mg for 10 days) significantly reduced deaths of severely sick COVID-19

patients in a major clinical trial [38]. In our scoping review, a higher dose of

corticosteroid has been widely used in severe pneumonia in selected Chinese

studies, but needs RCT to gain more solid and conclusive evidence. Other

treatments for severe pneumonia suggested by our review and the guidelines

contain empiric antimicrobial treatment [39-42] and mechanical ventilation,

nevertheless, details such as opportunity for advanced oxygen/ventilatory

support, tidal volumes and inspiratory pressure, and prone ventilation were not

presented in most selected studies.

Other findings in this review might have some new implications on

therapeutic strategy for severe pneumonia. The cytokine storm identified in

severe pneumonia might provide a reason and basis for continuous renal

replacement therapy or corticosteroids administration, but the effect on outcomes

needs to be validated. The fluid resuscitation strategy for patients with severe

pneumonia should be carefully modified according to our findings regarding the

complications, as in the setting of severe pneumonia-induced ARDS, acute

cardiac injury, and acute kidney injury, fluid resuscitation might increase the risks

of pulmonary edema, heart failure and kidney failure if using starches,

respectively.

Several limitations need to be acknowledged. First, some features of

severe pneumonia were noted in small numbers of studies, and the majority of

studies included small numbers of patients, so, the features such as

cerebrovascular disease, pharyngalgia, and hypersensitive troponin I might be

unrepresentative, and possibly lead to uncertainty in practical guidance. Second,

the inherent risk of confounding in the included studies would be high, as the

majority of studies were observational. Lastly, there was a wide range of

presentations recorded in the studies overall. To have a comprehensive

understanding on the features of severe pneumonia, we delineated the aspects with the minimum and maximum of the categorical data, and calculated overall ratio of each item in comorbidities, symptoms and complications. In future, there is a need for systematic inclusion of many points of data.

Collectively, this scoping review gives us a profiling regarding the demographics, comorbidities, clinical manifestations, complications, laboratory findings, therapies, and outcomes of severe pneumonia. The old age, some comorbidities and laboratory findings might be the predisposing factors of disease severity. Most Chinese studies were performed at the beginning of pandemic and ahead of the clear acknowledgement of COVID-19, the empirical therapy such as antivirals were used as the primary treatment for severe pneumonia. Also, as most data originate from China, the external validity of findings need to be confirmed with the studies from western countries. So, to better understand the disease and provide the guidance to treatment, multicenter- and large population-designed studies, with confounding variables controlled and long enough to accommodate follow-ups are urgently required in the future.

Table 1. The characteristics of the included studies

	Definition of severe pneumonia	Study type	Study institution	Severe pneumonia No.	Non-severe cases (No./%)	Clinical characteristics	Laboratory findings
Huang CL[3]	All patients had PaO2/FiO2≤300mmHg.	Retrospective, observational, single-center	Jin Yin-tan Hospital (Wuhan, China)	13	28 (68.3)	Comorbidities; Symptoms; Complications	Routine tests; Cytokines; Lymphocyte subsets
Liu JY[12]	SpO2≤93% or respiratory rates≥30 per min, PaO2/FiO2≤300mmHg.	Prospective, observational, single-center	Ditan Hospital (Beijing, China)	17	44 (72.1)	Comorbidities; Symptoms	Routine tests
Chen G[13]	SpO2≤93% or respiratory rates≥30 per min.	Retrospective, observational, single-center	Tongji Hospital (Wuhan, China)	11	10 (47.6)	Comorbidities; Symptoms; Complications	Routine tests; Cytokines; Lymphocyte subsets
Liu YL[14]	All patients had PaO2/FiO2≤300mmHg.	Retrospective, observational, single-center	Central Hospital of Wuhan, (Wuhan, China)	53	56 (51.4)	Comorbidities; Symptoms	Routine tests
Liu J[15]	SpO2≤93% or respiratory rates≥30 per min, PaO2/FiO2≤300mmHg.	Retrospective, observational, single-center	Union Hospital (Wuhan, China)	13	27 (67.5)	Comorbidities; Symptoms	Routine tests; Cytokines; Lymphocyte subsets
Wan SX[16]	SpO2≤93% or respiratory rates≥30 per min, PaO2/FiO2≤300mmHg.	Retrospective, observational, single-center	Three Gorges Central Hospital (Chongqing, China)	21	102 (82.9)	NA	Cytokines; Lymphocyte subsets
Chen L[11]	SpO2≤93% or respiratory rates≥30 per min, PaO2/FiO2≤300mmHg.	Retrospective, observational, single-center	Tongji Hospital (Wuhan, China)	14	15 (51.7)	NA	Cytokines; Lymphocyte subsets
Zhang JJ[17]	SpO2≤93% or respiratory rates≥30 per min, PaO2/FiO2≤300mmHg.	Retrospective, observational, single-center	No. 7 Hospital (Wuhan, China)	58	82 (58.6)	Comorbidities; Symptoms	Routine tests
Wan SX[18]	SpO2≤93% or respiratory rates≥30 per min, PaO2/FiO2≤300mmHg.	Retrospective, observational, single-center	Three Gorges Central Hospital (Chongqing, China)	40	95 (70.4)	Comorbidities; Symptoms; Complications	Routine tests
Li KH[19]	SpO2≤93% or respiratory rates≥30 per min, PaO2/FiO2≤300mmHg.	Retrospective, observational, multicenter	The Second Affiliated Hospital of Chongqing Medical University (Chongqing, China) / Three Gorges Central Hospital (Chongqing, China) / Yanzhuang Central Hospital (Jinan, China)	25	58 (69.9)	Comorbidities; Symptoms	Routine tests
Zheng SF[20]	SpO2≤93% or respiratory rates≥30 per min, PaO2/FiO2≤300mmHg.	Retrospective, observational, single-center	The First Affiliated Hospital, College of Medicine, Zhejiang University (Hangzhou, China)	74	22 (22.9)	Comorbidities; Symptoms	Routine tests; Cytokines; Lymphocyte subsets

Cao B[21]	SpO2≤93% or respiratory PaO2/FiO2≤300mmHg.	Open-label, individually randomized, controlled trial	Jin Yin-tan Hospital (Wuhan, China)	199	NA	Comorbidities	Routine tests
Giacomo G[22]	100% patients had severe pneumonia and almost all of them had ARDS requiring mechanical ventilation (Based on the information from the author).	Retrospective, observational, multicenter	72 hospitals in the coordinator center (Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy)	1591	NA	Comorbidities	NA

Routine tests included routine blood test, coagulation test, D-dimer, Liver and kidney function, cardiac biomarkers, c-reactive protein.

NA: Not available.

Reproduce.

	Antiviral therapy	Corticosteroid	Immunoglobulin	Antibiotic therapy	Nasal cannula	Non-invasive ventilation or high-flow nasal cannula	Invasive mechanical ventilation	Extracorporeal membrane oxygenation	Renal replacement therapy
Huang CL[3]	12/13 (92.3%) received antiviral therapies, oseltamivir (75 mg p.o. bid) was used. Effect was not evaluated and reported.	6/13 (46.1%) received methylprednisolone (40-120 mg qd). Effect was evaluated and reported.	NA	13/13 (100%)		8/13 (61.5%)		2/13 (15.3%)	
Liu JY[12]	11/17 (64.7%) received antiviral therapies, including oseltamivir (75 mg p.o. bid), or lopinavir and ritonavir tablets (200 mg p.o. bid), but the case number for each antiviral therapy was not reported. Effect was not evaluated and reported.	...received methylprednisolone, but not aimed to treat SARS-CoV-2 pneumonia, dosage was quite low (8 mg qd) or not described.	NA	14/17 (82.4%)	5/17 (29.4%)	3/17 (17.6%)	2/17 (11.8%)	NA	NA
Chen G[13]	Treated with oseltamivir (75 mg p.o. bid) and/or ganciclovir, but the case numbers for antivirals or each antiviral were not reported. Effect was not evaluated and reported.	Received methylprednisolone (40-80 mg qd), but the case number was not reported. Effect was not evaluated and reported.	NA	11/11 (100%) received antibiotic therapies, moxifloxacin or cefoperazone-sulbactam, but the case number for each antibiotic was not reported.	NA	9/11 (81.8%)	NA	NA	NA
Liu YL[14]	52/53 (98.1%) received antiviral therapies (46/52 (86.8%) received ribavirin, 14/52 (26.4%) oseltamivir, and 6/52 (11.3%) arbidol). No antiviral showed effect.	37/53 (69.8%), no effect was found.	29/53 (54.7%), no effect was found.	53/53 (100%)	NA	26/53 (49.1%)	NA	NA	NA
Wan SX[18]	40/40 (100%) received antiviral therapies, details were not available. Effect was not evaluated and reported.	21/40 (52.5%), effect was not evaluated and reported.	NA	35/40(87.5%)	NA	27/40 (67.5%)	1/40 (2.5%)	0/40 (0%)	4/40 (10.0%)
Zheng SF[20]	74/74 (100%) received antiviral therapies, including lopinavir-ritonavir combination, arbidol, favipiravir, and darunavir-cobicistat, but the case numbers for each antiviral were not reported. Effect was not evaluated and reported.	69/74 (93.2%), effect was not evaluated and reported.	49/74 (66.2%), effect was not evaluated and reported.	32/74 (43.2%)	NA	NA	10/74 (13.5%)	5/74 (6.7%)	NA
Cao B[21]	95/199 (48.2%) received antiviral therapies, lopinavir combined with ritonavir (400 mg and 100 mg, orally) were used. No effective outcomes were observed.	67/199 (33.7%), effect was not evaluated and reported.	NA	189/199 (95.0%)	NA	29/199 (14.6%)	32/199 (16.1%)	4/199 (2.0%)	9/199 (4.5%)
Giacomo G[22]	NA	NA	NA	NA	13/1591 (0.8%)	137/1591 (8.6%)	1150/1591 (72.3%)	5/498 (1.0%)	NA

Table S1. Critical appraisal for case-series

Only age and gender were considered for demographics.

Table S2. Critical appraisal for cross-sectional studies

	Were the criteria for inclusion in the sample clearly defined?	Were the study subjects and the setting described in detail?	Was the exposure measured in a valid and reliable way?	Were objective, standard criteria used for measurement of the condition?	Were confounding factors identified?	Were strategies to deal with confounding factors stated?	Were the outcomes measured in a valid and reliable way?	Was appropriate statistical analysis used?

Figure legends

Figure 1. Literature search results for identification, exclusion, and selection of studies. The literature search identified 4,824 articles. After discarding 1,883 duplicates, the titles and abstracts of 2,941 articles were screened. 63 articles were retrieved for full-text evaluation. Thirteen articles met our inclusion criteria for the final scoping review.
