Running Head:

ETI significantly and markedly reduces GI symptoms (CFAbd-Score), faecal M2-PK and Calprotectin

Keywords:

CFTR, modulation, gastro-intestinal (GI), patient reported outcome measure (PROM), faecal elastase

ETI significantly and markedly reduces GI symptoms (CFAbd-Score), faecal M2-PK and Calprotectin

Graphical Abstract

Statistically significant and clinically relevant sustained decline in GI symptoms using the CFAbd-Score in pwCF over 12 months of therapy with Elexacaftor-Tezacaftor-Ivacaftor (ETI) as part of the RECOVER study. Changes over time in total CFAbd-Scores as well as of the 5 included domains are shown before (0), as well as 1,2,6 and 12 months after initiation of ETI

Highlights

- The present study uses the first validated CF-specific patient reported outcome measure focusing on gastrointestinal symptoms (CFAbd-Score) to demonstrate that ETI leads to substantial and sustained reduction in GI-symptom burden

- Symptom improvement is rapid, being evident at 1 month, peaking 2 months and stabilising thereafter

- Previous studies assessing effects of ETI on GI-symptoms had generated conflicting results

- For the first time, significant improvements in faecal M2-pyruvate Kinase (M2-PK), a marker of cell proliferation were seen on ETI, in addition to reductions in faecal calprotectin as previously reported

ETI significantly and markedly reduces GI symptoms (CFAbd-Score), faecal M2-PK and Calprotectin

Abstract

Background: RECOVER is a multicentre post-approval study of Elexacaftor/Tezacaftor/Ivacaftor (ETI) in pwCF in Ireland and the UK. The CFAbd-Score is the first validated CF-specific patient reported outcome measure (PROM) focusing on gastrointestinal symptoms; it comprises 28 items in 5 domains. In a preliminary study, we previously reported reductions in abdominal symptoms (AS) in pwCF after 26 weeks of ETI-therapy using the CFAbd-Score.
Aim: to assess changes in AS in a second, large cohort and explore novel GI-biomarkers of gut inflammation and cell-proliferation in pwCF over one year of ETI-therapy.

Methods:
Participants were recruited as part of the RECOVER study at 8 sites (Ireland&UK). The CFAbd-Score was administered prior to ETI-initiation, and subsequently at 1,2,6 and 12 months on treatment. Faecal M2-pyruvate kinase (M2-PK) and calprotectin (FC) were quantified in samples collected at baseline, 1 and 6 months.

Results: 108 CFAbd-Scores and 73 stool samples were collected at baseline. After 12 months of ETI-therapy, total CFAbd-Scores had significantly declined (15.0±1.4→9.8±1.2pts/p<0.001), and so had all its five domains of "pain" (16.9±2.0pts→9.9±1.8pts/p<0.01), "GERD" (14.4±1.8→9.9±1.6/p<0.05), "disorders of bowel movements" (19.2±1.4→14.1±1.5/p<0.01), "appetite" (7.0±1.1→4.6±1.2/p<0.01) and "impaired-QoL" (13.3±1.9→7.5±1.5/p<0.001). Levels of M2-PK and FC significantly decreased during ETI-therapy.

Discussion: In-depth analysis of AS with the CFAbd-Score reveals a statistically significant, clinically relevant and sustained improvement with ETI. We attribute this to high sensitivity of the implemented CF-specific PROM, developed and validated following FDA-guidelines. Furthermore, for the first time during ETI-therapy a significant decline in faecal M2-PK, a marker of inflammation and cell-proliferation, was found, in parallel to FC.

ETI significantly and markedly reduces GI symptoms (CFAbd-Score), faecal M2-PK and Calprotectin

Introduction

Already at birth, most infants with cystic fibrosis (CF) have exocrine pancreatic insufficiency (PI). Malabsorption, malnutrition and growth failure follow PI, particularly with advancing age and evolving CF lung disease. Intestinal epithelial dysfunction, particularly in the setting of PI, can be associated with inflammation, dysbiosis and dysmotility, partial or complete bowel obstruction either in infancy with meconium ileus (MI) or later in life with constipation or distal intestinal obstruction syndrome (DIOS).(1) The nature of abdominal involvement in people with CF (pwCF) may result in a significant burden of abdominal symptoms (AS) leading to impairment in quality of life.(1-3) AS including reduced appetite, pain, flatulence and abdominal distention are almost universal, and are associated with abnormal imaging findings.(4-7)

Faecal calprotectin (FC), an extensively used biomarker for intestinal inflammation, has been found to be markedly elevated in pwCF, compared with healty controls (HC).(8) We have previously reported on elevated levels of FC, interleukin (IL)-1β, M2-pyruvate kinase (M2-PK) and neutrophil elastase (NE) in feces of pwCF compared to HC.(9) Specifically, pwCF reporting a high burden of abdominal pain displayed significantly elevated FC levels. PwCF and their care teams have ranked gastrointestinal presentations of CF as a high research priority in CF.(7,10) Abdominal manifestations, although they can be very troublesome, can be hard to characterize, challenging to effectively treat and receive less attention overall than pulmonary manifestations in pwCF.

The CFAbd-Score, the first CF-specific AS questionnaire and its scoring algorithm which weights different items and domains differently, was designed and validated according to FDA and COSMIN guidance.(4-6,9,11-13) It was developed in close collaboration with the CF community voice (pwCF, their proxies, as well as CF care-specialist of different professions: pediatricians, pulmonologists, gastroenterologists, nutritionalists, psychologists). The initial 5-sided version (JenAbd-Score (22)) was condensed to a one-sided PROM, the CFAbd-Score, including 28 items in 5 domains(4-6) with a 2-week recall period. The score ranges from a minimum of 0 to a maximum of 100 points with higher scores representing a more pronounced symptom burden. CFAbd-Scores correlate with CFTR-genotype and phenotype, as well as with history of abdominal surgery and both intestinal inflammation(9) and imaging findings(5) in pwCF.

In the last decade, the use of CFTR-modulating therapy has grown significantly among pwCF. The first CFTR modulator, ivacaftor (IVA) led to marked improvements in sweat chloride and end-organ function in those with responsive CFTR mutations, representing only a small minority (5%) of pwCF.(14-19) Recently, the triple combination modulator

ETI significantly and markedly reduces GI symptoms (CFAbd-Score), faecal M2-PK and Calprotectin

Elexacaftor-Tezacaftor-Ivacaftor (ETI) has demonstrated similar dramatic improvements in sweat chloride and end organ function, but is suitable for use in >90% of pwCF.(20-25) Collectively IVA and ETI are referred to as highly effective CFTR-modulating therapies (HEMT).

In early studies involving HEMT, improvement in the digestive system had only been indirectly captured by the substantial incremental improvement in the nutritional status of pwCF on treatment. As clinical trials of ivacaftor moved into younger ages, improvements in faecal elastase (FE-1) levels (marker of exocrine pancreatic insufficiency) in some cases were seen in the normal range.(14,17) This has been reproduced in real-world studies.(26,27) Use of ivacaftor has also been associated with improvements in gastric hyperacidity, markers of intestinal inflammation,(28) and the gut microbiome.(29) In a similar vein, ETI has been associated with improvements in FE-1 in younger children(30) and in gastrointestinal inflammation in older children and adults.(31)

While HEMT has been repeatedly shown to improve overall quality of life in CF as measured by CFQ-R,(20,32) data on AS have been more sparse, using different measures and producing differing results.(13,31) Using previously developed (non-CF) AS questionnaires like the PAGI-SYM, PAC-SYM, PAC-QoL or Peds-QL, as well as questionnaires developed for irritable bowel syndrome(31,33,34) and the abdominal domain of CFQ-R,(35) a high burden of GI symptoms in pwCF has been demonstrated. However, in a recent large post-approval study of ETI in the US, although changes in these symptom scores (PAGI-SYM, PAC-SYM, PAC-QoL) were statistically significant they were not of a magnitude considered clinically relevant.(31)

In contrast, using the CF-specific CFAbd-Score, we have previously demonstrated statistically and clinically significant improvements in AS in 107 pwCF aged ≥12 years from Germany (n=68) and the UK (n=39) over 26 weeks.(13) This study was limited in some aspects owing to marked differences in demographic features between German and UK populations with regard to age, *CFTR* mutations, exocrine pancreatic status, and recruitment time frame. While these issues were recognised by the authors, the need for a replicate study over a longer time period, linked to other gastro-intestinal outcomes was evident, hence the design and conduct of this aspect of the RECOVER study.

RECOVER (NCT04602468) is a multi-centre post approval study designed to examine the impact of ETI on a range of clinically relevant outcome measures in a real-world setting in pwCF in Ireland and the UK.

ETI significantly and markedly reduces GI symptoms (CFAbd-Score), faecal M2-PK and Calprotectin

Our aim in this study was to characterise the extent and timing of changes to abdominal symptoms and markers of intestinal inflammation and cell proliferation among pwCF starting treatment with ETI.

Methods

Participants

As part of the RECOVER study, participants who were either homozygous for the F508del mutation (FF) or heterozygous for F508del and a minimum function mutation (FMF) were enrolled at 8 clinical sites across Ireland and the UK prior to initiation of ETI as part of usual care. Data on baseline characteristics, and longitudinal data on height, weight and BMI, collected every 3 months, were taken from medical notes. Research Ethics Committees approved the study and informed consent and assent was obtained.

Symptoms assessment - CFAbd-Score

The CFAbd-Score, a PROM consisting of 28 questions in 5 domains, was applied prior to ETI-initiation, and subsequently at 1,2,6 and 12 months on treatment. Total CFAbd-Scores and domain scores range from 0 to 100 points, with higher scores indicating higher AS-burden.(6) Total CFAbd-Scores and domains scores are calculated using a scoring algorithm that weights items and domains differently to optimize sensitivity. CFAbd-Score questionnaires were administered to participants by research staff at sites. Pseudonymized questionnaires were captured, processed and scored centrally at the CF Center in Brandenburg and der Havel, Germany.

Collection and processing of stool specimens

Stool specimens were collected at baseline and one and six months after initiation of ETI therapy. Participants were provided in advance with equipment to collect and refrigerate stool samples on the morning of each study visit. After collection, stool samples were split at the study site. 5-10g aliquots were frozen at -80C, with one aliquot sent on dry ice to the CF Center in Brandenburg an der Havel, Germany for analysis of calprotectin, M2-PK and FE-1. Further aliquots were frozen at -80C and shipped to central labs at Children's Health Ireland and stored for future microbiome and other analysis.

Markers of faecal inflammation

Calprotectin was measured from frozen stool samples using the DiaSorin LIAISON® Calprotectin assay (DiaSorin Inc. Stillwater, MN 55082, US), a sandwitch-test using two

ETI significantly and markedly reduces GI symptoms (CFAbd-Score), faecal M2-PK and Calprotectin

monoclonal antibodies, an in-vitro-diagnostic chemiluminescent immunoassay (CLIA), range 5-800µg/g; Liaison®XL. M2-PK was measured using the ScheBo Tumor M2-PK kit (ScheBo Biotech, Giessen, Germany), Reader ELx800TM (Fa.BioTek) an ELISA with a range from 1-20U/ml. Stools were extracted into ready-to-use extraction buffer (anti-bio-POD-step complex) using the ScheBo® Master Quick-Prep™ and each 50µl of stool extract was analyzed. FE-1 was measured with a sandwich-test using two monoclonal antibodies, an in-vitro-diagnostic chemiluminescent immunoassay (CLIA)(DiaSorin LIAISON® Elastase-1 Assay (DiaSorin Inc. Stillwater, MN 55082Calpro, San Diego, CA, US). Range: 0.2µg/g-800µg/g stool, Liaison®XL.

Statistical analysis

Linear mixed-effects models for repeated measures were used to test for differences in the CFAbd-Score and its five domains, including time from therapy start (in months) as fixed effect as well as variables sex (M/F), previous previous CFTR-modulating therapy (yes/no), genotype (F508del-homozygous/heterozygous) and group age (<18/≥18) as covariates. Significant first-order interactions of these covariates and time were selected using backward-elimination procedures. Total CFAbd-Score and domains were log-transformed to satisfy normality conditions on residuals. Results are reported as means±error of mean (SEM) in the original scale. For between-group (cross-sectional) comparisons of FC, FE-1 and M2-PK all data available at each time-point was used. For FE-1 and M2-PK longitudinal comparisons, the non-parametric Wilcoxon signed-rank test for paired samples was used; FE-1 concentrations from pwCF identified as pancreatic sufficient (PS) at baseline were excluded from the longitudinal FE-1 comparisons. As normal reference values for FC, M2-PK and FE-1 concentrations, we considered the cutoff values of 50µg/g, 4U/ml and 200µg/g, respectively.(8,36,37)

ETI significantly and markedly reduces GI symptoms (CFAbd-Score), faecal M2-PK and Calprotectin

Results

Participants

A total of 117 pwCF were recruited to the 12 and over age cohort of the RECOVER study, 108 of whom completed the CFAbd-Score at baseline and at least one other time point. Demographics and clinical information is shown in Table 1.

Table 1. Demographic and clinical information of participants included in the study.

Participants		n (%)

CFAbd-Score

Total CFAbd-Scores improved significantly from baseline over one year of treatment, as did subscores for "pain", "GERD", "disorders of appetite", "QoL" and "disorders of bowel movements" (Fig.1-Table 2). Improvements are rapid, with the major improvements occurring in the first month and attaining a maximum improvement at 2 months for total scores and most of the domains (Fig.2).

ETI significantly and markedly reduces GI symptoms (CFAbd-Score), faecal M2-PK and Calprotectin

Overall, in the GERD domain, adult pwCF (age≥18) reported significantly higher scores than adolescents (baseline [mean±SEM]: 16.2±2.9 vs 13.1±2.3, 12-months: 15.2±3.2 vs 7.0±1.8; main-effect-p=0.003). Females reported significantly higher scores than males in the DA domain (baseline [mean±SEM]: 4.5±0.1 vs 10.0±0.3, 12-months: 7.9±0.4 vs 2.2±0.1; main-effect-p=0.01). No other differences regarding sex, previous CFTR-modulator therapy, genotype group or age (<18/≥18) were observed.

Figure 1. Baseline (solid red line), 2-month (green line) and 12-month (blue line) means of total CFAbd-Score and its five domains, i.e. pain, gastroesophageal reflux disease (GERD), disorders of bowel movement (DBM), disorders of appetite (DA) and impairment of quality of life (QoL).

ETI significantly and markedly reduces GI symptoms (CFAbd-Score), faecal M2-PK and Calprotectin

Figure 2. Mean scores (mean±SEM) at baseline (n=108) and after one (n=97), two (n=72), six (n=103) and 12 (n=81) months of ETI therapy for: A) total CFAbd-Score, B) pain domain, C) gastroesophageal reflux disease (GERD) domain, D) disorders of bowel movement (DBM) domain, E) disorders of appetite (DA) domain and F) impairment of quality of life (QoL) domain. Significant changes with respect to baseline values are labelled as * p<0.05, ** p<0.01, *** p<0.001.

Faecal markers of inflammation and cell proliferation

Overall, 93 participants provided at least one stool sample for analysis of FC, FE-1 and M2-PK. Specifically, stool samples from 73, 74 and 62 patients were collected at baseline, 1 month and 6 months, respectively. For analysis of FC changes over the six-month observation time frame, a linear mixed-effects model was used including all available samples at each time point. For M2-PK and FE-1, however, only data from pwCF that provided stool samples at all three time points was analysed (n=43 for M2-PK and n=42 for FE-1).

FC concentrations decreased significantly from baseline to 1 month (mean±SEM) (70±8.9µg/g→27.4±3.4µg/g/$p<0.0001$). This difference was maintained at 6 months (27.3±3.4µg/g). In parallel, median M2-PK-concentration decreased significantly by 76% from baseline to 1 month (median [IQR]): 12.0U/ml [4.4-20.0]→2.9U/ml [1.0-8.0]/$p<0.0001$), with little change thereafter (median [IQR]: 2.7U/ml [1.0-10.7])(Fig.3). There was a strong correlation between FC and M2-PK at baseline (Spearman's rho=0.50/$p<0.0001$, n=73). This correlation was weaker at 6 months (Pearson's r=0.34/$p<0.05$, n=61).

ETI significantly and markedly reduces GI symptoms (CFAbd-Score), faecal M2-PK and Calprotectin

Markers of pancreatic sufficiency

At baseline 87.5% (63/72) of participants had levels of FE-1 activity <5µg/g, indicative of severe pancreatic dysfunction. At 6 months, 85% (51/60) of participants had levels <5µg/g. While median FE-1 concentrations were significantly higher at 6 months compared to baseline (median [IQR]: 0.3µg/g[0.1-3.1], 0.2µg/g[0.1-0.4]/p=0.003), this was not at a level where clinical effects would be apparent. 2/60 participants had FE-1 concentrations >100µg/g (123µg/g and 111µg/g) at 6 months.

Figure 3. Values at baseline, month 1 and month six for (A) faecal calprotectin (n=73 (baseline), 74 (month 1) and 62 (month 6)), (B) M2-pyruvate kinase (n=43) and (C) faecal elastase (n=42). Horizontal lines in boxes of all boxplots depict median values. FC mean values and SEM resulting from the linear mixed-effects model are: 70±8.9 (baseline), 27.4±3.4 (1 month) and 27.3±3.4 (6 months).
Dashed lines represent the corresponding normal reference values for each parameter. P values are labelled as ** p<0.01 and **** p<0.0001 compared to baseline values.

Inflammatory and proliferation-parameters and correlations with abdominal symptoms

At baseline, a significant positive correlation between FC and both the "Disorders of Appetite" (Pearson's r=0.32/p=0.005) and the QoL (Pearson's r=0.29/p=0.01) domains were observed. Baseline M2-PK concentrations correlated positively with baseline total CFAbd-Score (Spearman's rho=0.31/p=0.001) and the Pain domain (Pearson's r=0.32/p=0.01). FE-1 did not correlate with the CFAbd-Score or any of its five domains.

At month six, there were no correlations with FC. M2-PK concentrations still correlated with total CFAbd-Scores (Spearman's rho=0.31/p=0.02), as well as now with GERD scores (Spearman's rho=0.31/p=0.02). Furthermore, QoL domain scores positively correlated with FE-1 concentration (Pearson's r=0.29/p=0.03).

ETI significantly and markedly reduces GI symptoms (CFAbd-Score), faecal M2-PK and Calprotectin

Discussion

Previously, intestinal manifestations did not receive much attention due to the intrinsic complexity in their characterization and treatment. Nowadays, intestinal manifestations in pwCF are acknowledged to result in a high burden of symptoms and their resolution was listed as second most important of the 10 top research priorities in CF.(4,7,9,10) Nevertheless, although the use of highly effective CFTR-modulating therapy including ivacaftor and ETI has been shown to improve general Quality of life and GI manifestations in PwCF,(17,28,38) the use of different PROMs to assess changes in AS led to conflicting results.(13,31) Furthermore, data on ETI effects on gastrointestinal manifestations and their link to other outcomes, e.g. markers in stool, is still scant.

The aim of this study was to characterise the extent and timing of changes to AS and intestinal inflammation and cell proliferation markers among pwCF starting ETI-treatment. Accordingly, the present study fills the need for a thorough GI-symptom assessment in a prospective study including a homogeneous and very well controlled cohort of pwCF receiving ETI, including series of consecutive time points, linked with markers of intestinal inflammation and cell proliferation.

Early results obtained with the CFAbd-Score in a longitudinal study, including 107 pwCF aged ≥12 years from Germany and the UK receiving ETI treatment over a period of 26 weeks,(13) had revealed marked declines for the total PROM (-29%) and its five domains. However, although the reduction in symptoms ranging between -23% and -67% was clearly within the margin quoted as clinically significant, changes in CFAbd-Scores revealed marked differences between both German and British cohorts. Specifically, improvement in the 68 German pwCF was markedly higher than the improvement in the 39 British pwCF, which was attributed to the marked differences in demographic features of German and UK pwCF, e.g. in regard to age, *CFTR* mutations, PS/PI, and recruiting time frame.

In contrast, the GALAXY study used previously developed (non-CF) AS-questionnaires including the PAGI-SYM, PAC-SYM, PAC-QoL, as well as a modified Bristol stool scale.(31,33,34) Although the reported changes in GI symptoms in 267 pwCF followed up before and during ETI therapy were statistically significant, according to the authors they lay below the margin of clinical significance.(31) Furthermore, recently a smaller single center retrospective observational study assessed changes in CFQ-R scores during ETI.(39) In contrast to other CFQ-R subdomains, no improvement in the GI symptoms of "Eating Problems", "Weight" and "Digestive Problems" was observed.

As part of the RECOVER study, we have thoroughly investigated longitudinal changes in AS assessed with the CF-specific CFAbd-Score from 108 pwCF aged 12 years and older. The

ETI significantly and markedly reduces GI symptoms (CFAbd-Score), faecal M2-PK and Calprotectin

total CFAbd-Score, measured at baseline, 1, 2, 6, and 12 months after ETI initiation declined by 41% after 2 months, which for the total CFAbd-Score and four domains accorded to the lowest AS-burden. Thereafter, and up to 12 months of observation, a slightly increasing trend was seen in some domains, which remained significantly lower than baseline at 12 months. Except for "Disorders of Bowel Movement", scores for all 5 domains were significantly lower than baseline at each observed time point.

Similarly to previous publications regarding the impact of HEMT on inflamation in pwCF,(31,40) FC in this study decreased after 1, 2 and 6 months of therapy and a significant correlation between baseline FC and the abdominal pain domain in the CFAbd-Score was found. This result concurs with a previous cross-sectional study with the CFAbd-Score, wherein FC was found to be elevated in PwCF suffering from a high burden of pain.(9) This finding additionally corresponds with studies revealing a HEMT-induced decrease in inflammation in pwCF in different organ systems such as the lower- and upper-airway.(41,42)

Unlike the study by Schwarzenberg et al.,(31) during ETI therapy FE-1 concentrations appeared to significantly increase in our cohort. However, this increase occurred in only a subset of participants and did not reach a level likely to be of clinical relevance. After 6 months of ETI, only 2/60 PwCF had FE-1 values above 100µg/g, but below the pancreatic sufficiency range considered to be above 200µg/g. This contrasts with the response observed for ivacaftor in young age cohorts, by which PwCF with a gating mutation maintain or even re-gain some degree of pancreatic sufficiency.(37,43,44)

To our knowledge, this is the first time that a decrease in faecal M2-PK associated with the use of ETI has been reported. The dimeric PK, elevated in 32/43 (74.4%) of the study participants with a median at baseline of 12U/ml (normal: <4.0U/ml(36)), declined significantly after one month, and remained low after six months of therapy (2.9 and 2.7U/ml, respectively). This finding may be of particular relevance, as M2-PK has not been deemed to directly represent inflammation.(45-48) Instead, it reflects epithelial turnover and it has been reported to be expressed in most human tumours. Herein it is deemed to play a central role in metabolic reprogramming of cancer cells being essential in their indiscriminate proliferation, survival, and tackling apoptosis.(49) Correspondingly, an increased epithelial turnover has also been linked to elevated rates of GI malignancies in pwCF and, consequently, elevated levels of M2-PK in stool of pwCF may be hypothesized to be correlated with their higher risks of colorectal cancer.(50) Interestingly, a number of studies are presently examining anti-M2-PK therapies aiming at reducing cancer risks by inhibiting the mediators' putative cell-proliferating properties.(49,51)

Several authors have recently projected that the improved survival in pwCF together with the higher predisposition and earlier onset of CFTR-associated intestinal malignancies will lead

ETI significantly and markedly reduces GI symptoms (CFAbd-Score), faecal M2-PK and Calprotectin

to higher cancer incidences in this cohort.(28,43,52) In contrast, this novel finding of reduced faecal M2-PK with ETI treatment could be a notable finding, perhaps suggesting down-regulation of carcinogenic effects of CFTR-deficiency. Such fundamental roles of CFTR in cellular processes such as foetal development, epithelial differentiation/polarization, and regeneration, as well as in epithelial–mesenchymal transition (EMT) have recently been reviewed by Amaral et al.,(53) wherein the authors address dysfunctional CFTR as a possible promotor of cancer progression. Re-constitution of CFTR function by ETI could therefore be hypothesized to have effects of a tumor suppressor. Further work will be needed to establish this.

Conclusion

This study adds to the growing evidence that ETI reduces GI-symptoms in pwCF, highly significant findings being likely due to the sensitivity of the CF-specific CFAbd-Score used to measure symptoms in this study. GI symptoms seem to be at their minimum at two months after treatment initiation. Similar to others, we have confirmed a significant improvement in gut inflammation with ETI use in pwCF, as measured by FC.

Finally, to the best of our knowledge for the first time, we demonstrate a significant improvement with ETI in faecal levels of M2-PK, a marker of cell turnover and a biomarker for colorectal carcinoma.
Collection of further longitudinal data and biological samples as part of the RECOVER study is ongoing.

ETI significantly and markedly reduces GI symptoms (CFAbd-Score), faecal M2-PK and Calprotectin

Conflict of interest

JGM reports independent grants and speaker/board honoraria from Vertex, Chiesi, Abbvie and Viatris outside the submitted work.

CZ, FD and AB declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest

PMN reports independent grants and speaker/board honoraria from Vertex outside the submitted work.

JCD and her institution have received fees for Advisory Board participation, clinical trial leadership and speaking engagements from Vertex Pharmaceuticals in the field of CFTR modulators but not directly related to this study, and from AbbVie, Arcturus, Boehringer Ingelheim, Eloox, Enterprise Thearpeutics and Novartis outside the scope of this work.

Acknowledgements:

We would like to acknowledge the dedication and commitment of people with CF and their parents who participated in this study, the CF care teams at the study sites, the RECOVER site staff and coordinating team. Funding for this study was from Cystic Fibrosis Foundation (MCNALL19K0), CF Trust (VIA118) and CF Ireland.
JCD is supported by the National Institutes of Health & Care Research through the Imperial Biomedical Research Centre, the Brompton Clinical Trials Facility and a Senior Investigator Award. The site is supported as part of the CF Trust's Clinical Trials Accelerator Platfor, (CTAP).
Furthermore, we would like to acknowledge Karina Börner and Yvonne Schimpf (Brandenburg an der Havel) for their assitance in laboratory.
