27 **Short title:** Atrial fibrillation and claudin-5

28 **Clinical Perspective**

29 **What Is New?**

- 30 1. This is the first study to find the decreased expression of claudin-5 (Cldn5) with prominent
31 muscle atrophy in the left atrial appendage of atrial fibrillation (AF) patients.
- 32 2. Knockdown of Cldn5 in the left ventricle via shRNA adeno-associated virus (AAV) infection
33 caused myocardial atrophy and arrhythmia including ST elevation, replacement of P-waves
34 with f-waves, and absence of P-waves prior to QRS.
- 35 3. The protein levels of CACNA2D2, CACNB2, MYL2 and MAP6 were significantly
36 downregulated after Cldn5 deficiency.

37 **What Are the Clinical Implications?**

38 The present findings may improve our understanding of the role of Cldn5 in the
39 pathophysiology of AF and provide a new therapeutic target for preventing AF.

40 **Nonstandard Abbreviations and Acronyms**

41 AF: atrial fibrillation; Cldn5: claudin-5; TEM: transmission electron microscope; AAV: adeno-
42 associated virus; LVAWd: LV anterior wall diameter at diastole; CACNA2D2: calcium channel,
43 voltage-dependent, alpha 2/delta subunit 2; CACNB2: calcium channel, voltage-dependent, beta
44 2 subunit; MYL2: Myosin light chain 2; MAP6: Microtubule-associated protein 6; MMP:
45 mitochondrial membrane potential; TJP1: tight junction protein 1; CAR: coxsackievirus-
46 adenovirus receptor; TMT: tandem mass tagging

47

48 **Background:** Although it is critically important to understand the underlying molecular and
49 electrophysiological changes that predispose to the induction and maintenance of
50 atrial fibrillation (AF), the underlying mechanism of AF is still poorly defined. AF is
51 characterized as the electrophysiological and membrane integrity abnormality of the atrial
52 cells, and claudin-5 (Cldn5), a tight junction protein, may be involved in the pathophysiology of
53 AF, however, the role of Cldn5 in AF is unknown.

54 **Methods:** Left atrial appendages from the enlarged left atrium were obtained from AF patients
55 undergoing modified radiofrequency ablation maze procedure and normal left atrial appendages
56 were obtained from non-AF donors. Western blot, immunofluorescence, transmission electron
57 microscope (TEM), and proteomics analysis were performed to screen the specific protein
58 expression and signal pathway changes in AF heart tissue vs. non-AF heart tissue. In addition,
59 Cldn5 shRNA or siRNA adeno-associated virus (AAV) were then injected into the mouse left
60 ventricle or added into HL1 cells respectively to knockdown claudin-5 in cardiomyocytes to
61 observe whether the change of Cldn5 influences electrophysiology and affects those protein
62 expressions stem from the proteomic analysis. Mitochondrial density and membrane potential
63 were also measured by Mito tracker staining and JC-1 staining under the confocal microscope *in*
64 *vitro*.

65 **Results:** The protein level of claudin-5 was significantly decreased in cardiomyocytes from the
66 left atrium of AF patients compared to non-AF donors. Proteomics analysis showed that 83
67 proteins were downregulated and 102 proteins were upregulated in the left atrial appendage of
68 AF patients. Among them, CACNA2D2, CACNB2, MYL2 and MAP6 were dramatically
69 downregulated. KEGG pathway analysis showed these changes would lead to hypertrophic
70 and/or dilated cardiomyopathy. Cldn5 shRNA AAV infection induced-Cldn5 deficiency caused
71 severe cardiac atrophy and arrhythmias in mice. The decreases in both mitochondrial numbers
72 and mitochondrial membrane potential (MMP) were also observed *in vitro* after Cldn5
73 knockdown by siRNA. Finally, western blot analysis confirmed the protein level of CACNA2D2,
74 CACNB2, MYL2 and MAP6 were downregulated after Cldn5 knockdown *in vivo* and *in vitro*.

75 **Conclusions:** We demonstrated for the first time the deficiency of Cldn5 in cardiomyocytes in
76 the left atrium of AF patients. The mechanism of AF might be associated with Cldn5 deficiency-
77 associated downregulation of CACNA2D2, CACNB2, MYL2 and MAP6, and mitochondrial
78 dysfunction in cardiomyocytes.

79 **Key Words:** Atrial fibrillation; Claudin-5; Cardiac atrophy; Proteomics analysis; Mitochondrial
80 dysfunction

81 **Introduction**

82 Atrial fibrillation (AF) is the most common arrhythmia encountered in clinics.¹
83 Disorganization of electrical impulses in the heart causes a rapid and irregular heart rhythm and
84 thus AF, which leads to substantial morbidity, mortality, and socioeconomic burden worldwide.²
85 ³ Pathogenic mutations of numerous genes have been causally linked to AF, of which the
86 majority encode ion channels, cardiac structural proteins, and gap junction channels.^{4,5} Gap and
87 tight junctions are the major intercellular junctions that play important roles in cellular
88 communication and structural integrity. In the heart, gap junctions comprised of connexins (Cxs)
89 form intercellular conduits responsible for electrical coupling and rapid coordinated action
90 potential propagation between adjacent cardiomyocytes. Despite accumulating clinical evidence
91 showing that gap junction protein Cx40 and Cx43 abnormalities are associated with AF,⁶⁻⁹ there
92 are few investigations for the effects of another cell-cell contact, tight junctions, on
93 electrophysiological properties in human and murine hearts.

94 Claudin-5 (Cldn5) is a transmembrane tight junction protein that controls endothelial and
95 epithelial permeabilities.¹⁰ Numerous investigations about the role of Cldn5 have been focused
96 on the blood-brain barrier in the last decades. Interestingly, clinical studies indicate that the level
97 of Cldn5 is reduced in human failing hearts.^{11,12} Our previous study demonstrated that Cldn5
98 was expressed in human and murine cardiomyocytes and regulated mitochondrial dynamics by
99 promoting mitochondrial fusion and inhibiting mitochondrial fission, which exerted its protective
100 effect against ischemia insult.¹³ However, the contribution of Cldn5 to cardiac electrophysiology
101 remains poorly defined.

102 In the current study, we clinically investigated the association of Cldn5 expression with
103 myocardial electrophysiological, morphological, and molecular characteristics in the left atrial
104 appendages of AF patients. Using the Cldn5 shRNA AAV approach, the relationship between
105 Cldn5 deficiency and cardiac electro-structural remodeling was evaluated in mouse heart. The
106 proteomic study was used to assess the protein profile in human left atrial appendages, and
107 western blot was used to confirm the changes of candidate proteins involved in myocardial

108 dilation and atrophy signaling pathways in AF patients' myocardium and in Cldn5 deficient
109 murine hearts. Finally, cell culture was used to assess Cldn5 knockdown on the mitochondrial
110 density and mitochondrial membrane potential by using Cldn5 siRNA in HL-1 cells. We show
111 that Cldn5 is critical for maintaining normal cardiac morphology and electrophysiology, and
112 downregulation of Cldn5 contributes to cardio-electric disturbance and myocyte atrophy as well
113 as myocardial dilation, which may underly the pathogenesis of AF and lead to novel ways to
114 treat arrhythmias in patients.

115 **Methods**

116 All procedures were performed in accordance with our institutional guidelines for animal
117 research that conforms to the Guide for the Care and Use of Laboratory Animals, and this study
118 was approved by the Ethical Committee of Zunyi Medical University, Zhuhai Campus. Mice
119 were kept in standard housing conditions with a light/dark cycle of 12 h and free access to food
120 and water.

121 **Human heart sample isolation**

122 With the approval from a local human research ethics review, left atrial appendages were
123 obtained from patients with severe AF accompanied by rheumatic mitral valve diseases
124 undergoing modified radiofrequency ablation maze procedure or normal control from organ
125 donors that were not used for heart transplantation but had no history of AF and major
126 cardiovascular diseases. Then the tissues were used for western blot, immunofluorescence, and
127 proteomic analysis.

128 **Echocardiography and Electrocardiography**

129 The AF patients were diagnosed by electrocardiography, and echocardiography was adopted
130 to observe the heart morphology. Cardiac function was evaluated in mice after 4 weeks of Cldn5
131 shRNA AAV intramyocardial injection by echocardiography and electrocardiography. For
132 echocardiography, using a Vivo-3300 ultrasonic system (VisualSonics, Toronto, ON, Canada)
133 equipped with a 30 MHz high-resolution probe. Mice were anesthetized with inhalational
134 isoflurane at a concentration of 1.5% and two-dimensional parasternal long-axis images of the
135 left ventricle (LV) were obtained at the level of the papillary muscles. The LV anterior wall

136 diameter at diastole (LVAWd) was measured. For electrocardiography, mouse
137 electrocardiography of Techman signal collection and analysis system (BL-420I) were used to
138 track arrhythmias and ventricular premature beat (VPB).

139 **Adeno-associated virus (AAV)-mediated Cldn5 knockout**

140 C57BL/6 male mice (aged 8–12 weeks, weighing 20–25 g) were anesthetized with a mixture
141 of xylazine (5 mg/kg, intraperitoneal) and ketamine (100 mg/kg, intraperitoneal). Cldn5 shRNA
142 adeno-associated virus (AAV) was injected to the left ventricle by 3-5 points. All mice were
143 under investigation for 4 weeks after Cldn5 shRNA injection to make sure the Cldn5 gene in the
144 myocardium have been successfully knockdown.

145 **Tandem mass tagging proteomics analysis**

146 The primary experimental procedures for tandem mass tagging (TMT) proteomics analysis
147 include whole-proteome preparation, trypsin digestion, TMT labeling, high-performance
148 pressure liquid chromatography fractionation, LC- MS/MS analysis and data analysis. Raw data
149 were analyzed using GO Annotation (<http://www.ebi.ac.uk/GOA/>), Domain Annotation
150 (InterProScan) and KEGG Pathway Annotation (KEGG online service tools KAAS mapper).
151 The protein-protein interaction networks stemming from a computational prediction were
152 analyzed in STRING (<https://string-db.org/>).

153 The resulting MS/MS data were processed using Proteome Discoverer search engine
154 (V2.4.1.15) against Homo_Sapiens_9606_PR_20210721.fasta (78,120 sequences) concatenated
155 with reverse decoy database. The parameters were set as follows: (1) trypsin (full) was specified
156 as the cleavage enzyme; (2) two missed cleavages were allowed; (3) the minimum peptide length
157 was six amino acids; (4) the maximum number of modifications per peptide was 3; (5) the mass
158 tolerance for precursor ions was 10 ppm in the first search; (6) fragment ion mass tolerance was
159 0.02 Da; (7) Carbamidomethylation on cysteine was fixed modification; (8) oxidation on
160 methionine and N-terminal acetylation were variable modification; and (9) false discovery rate
161 was adjusted to 1%. Student's t-test was used to evaluate the significant differences. The proteins
162 with a fold change of ≥ 1.50 or $\leq 1/1.5$ and p-value < 0.05 were considered differentially
163 expressed proteins (DEPs).

164 **Immunofluorescence and Wheat Germ Agglutinin (WGA) staining**

165 Cldn5 was localized by double-label immunofluorescence confocal microscopy, and their
166 overlap was quantified. Briefly, the human and mice heart tissues were fixed in 4%
167 paraformaldehyde, embedded in paraffin, and sections (3–5 μ m thickness) were stained with
168 primary antibodies for Cldn5-Alexa Fluor 488 (Invitrogen, Catalog#352588), CD31 (Proteintech,
169 Catalog#11265-1-AP) or Tomm20 (Abcam, ab186734) for 1h at room temperature. Then
170 Fluorescein donkey anti-rabbit IgG Alexa Fluor 594 was incubated for 30 min in the dark before
171 confocal microscopic observation. In addition, the cross-sectional areas of the cardiomyocytes in
172 human and mouse myocardium were observed by fluorescein-conjugated wheat germ agglutinin
173 (WGA; 5 μ g/mL, 25530, AAT Bioquest, USA) staining and evaluated by calculating the single
174 myocyte cross-sectional areas measured by ImageJ software (National Institutes of Health, USA).

175 **Cell culture, mitochondrial number and mitochondrial membrane potential ($\Delta\psi$ m) analysis**

176 Mouse Cldn5 siRNA (RiboBio, siG2302130920115720) was transfected by lipo 2000 to
177 knock down the expression of Cldn5 in HL-1 cells. Then the mitochondria were imaged by
178 Mitotracker Green FM (Invitrogen, M7514) and the mitochondrial membrane potential was
179 examined by a JC-1 staining kit (Beyotime, C2006). The intensity of the fluorescence was
180 measured by Image J.

181 **Western Blot Analysis**

182 Proteins were obtained from whole hearts or HL-1 cells. Samples containing equal amounts of
183 protein (10 μ g) were separated by 10% SDS-PAGE and transferred onto PVDF membranes. The
184 membranes were blocked with 5% skimmed milk at room temperature for 2 h and then incubated
185 overnight at 4°C with the primary antibody. The following antibodies were used for the Western
186 blotting analysis: Cldn5 (Abcam, ab172968), CACNA2D2 (Abcam, ab173293), CACNB2
187 (Abcam, ab253193), MYL2 (Affinity, DF7911), MAP6 (Santa Cruz, sc-137036). After being
188 incubated with goat anti-rabbit or goat anti-mouse secondary antibody for 1 h at room
189 temperature, the blots were detected and quantified by densitometry using the Image J Analysis
190 software.

191 **Transmission Electron Microscopy**

192 Human and mouse heart samples were fixed in 2% glutaraldehyde, phosphate-buffered to pH
193 7.4 and post-fixed with 1% OsO₄. After dehydration, the samples were incubated in propylene
194 oxide followed by embedding in a mixture of Epon 812 and Araldite. Ultrathin sections obtained
195 by an Em UC7 Ultramicrotome (Leica) were collected on TEM nickel grids and analyzed using a
196 TEM (JEM-1400 Plus, JEOL) at 100 kV.

197 **Statistical analysis**

198 All experiments were expressed as the mean \pm SEM and $p < 0.05$ was considered to indicate
199 statistical significance. The paired *t*-test was used for comparisons between the two groups. One-
200 way ANOVA with post hoc analysis by the Fisher exact probability test was employed for
201 multiple comparisons. All analyses were performed using SPSS 13.0 software (SPSS Inc.,
202 Chicago, IL).

203 **Results**

204 **Claudin-5 is downregulated in cardiomyocytes from Af patients' left atrial appendages**

205 Diagnosis of AF is confirmed by a 12-lead electrocardiogram (ECG) and an
206 echocardiographic observation in an apical four-chamber view. The representative images of
207 ECG and echocardiography were presented in Figure 1A in an AF patient. A significantly
208 enlarged left atrium (LA) was observed (red dashed box in Figure 1A). To mitigate the risk of
209 stroke, we adopted a modified radiofrequency ablation maze procedure to ablate AF triggers and
210 modify AF substrates (Figure 1B, right panel), which is proven more efficient than the catheter-
211 based introduction of lesions (Figure 1B, left panel). The excised LA appendages were then used
212 for western blot and immunofluorescence (IF) to observe the Cldn5 expression and
213 cardiomyocyte morphology. The protein level of Cldn5 was significantly decreased in the AF
214 group (Figure 1C). The IF images further showed the localization of Cldn5 on mitochondria and
215 confirmed the decreased expression of Cldn5 in cardiomyocytes (Figures 1D and 1E). Left atrial
216 appendage sections stained with FITC-WGA also showed the decreased cross-section of
217 cardiomyocytes in the AF group when compared with non-AF.

218 **Claudin-5 knockdown causes cardiac atrophy and disrupts cardiac rhythm in mice**

219 In-vivo studies in C57BL6 mice were performed to evaluate the influence of cardiac Cldn5 on
220 cardiac morphology and electrophysiology. Cldn5 shRNA AAV was injected in the murine left
221 ventricular myocardium for 4 weeks to knock down the Cldn5 as shown in Figure 2A. Western
222 blot showed AAV infection caused a 69.5% reduction of Cldn5 in the LV (Figures 2B and 2C).
223 The thickness of the LV anterior wall was also reduced by 45% in the shRNA AAV infection
224 group (Figures 2D and 2E). Cardiac conduction was assessed by II-lead ECG specialized for
225 murine, which detected the arrhythmia including ST elevation, replacement of P-waves with F-
226 waves and absence of P-waves prior to QRS (Figure 2F). Additionally, LV sections stained with
227 FITC-WGA showed a decreased cross-section of cardiomyocytes in the shRNA infection group
228 compared to the control (Figures 2G and 2H).

229 **Overview of tandem mass tag-based proteomic data**

230 Cardiac tissues from AF and non-AF patients' left atrial appendages were undertaken
231 proteomic analysis. By strict quality control, we obtained a total of 6,36,881 spectrums (3,05,015
232 matched), and 50,211 peptides (45,784 unique peptides) were detected among them. Finally,
233 5,648 proteins were identified, 5,365 of which were quantified (Figure 3A). Biological replicates
234 were validated by the relative standard deviation distribution, which displayed the precision and
235 reproducibility of our proteomic datasets (Figure 3B). Following statistical analysis, 185 proteins
236 with fold-change ≥ 1.50 or $\leq 1/1.5$ and p -value < 0.05 were considered the DEPs. Among them, a
237 total of 102 up-regulated and 83 down-regulated DEPs were identified when comparing AF with
238 non-AF patients' heart samples (Figure 3C). These data were clustered on a heatmap to reveal
239 hierarchical commonality in protein abundance for samples within each cardiac tissue type, yet
240 differences in protein abundance when comparing AF and non-AF heart tissues (Figure 3D).
241 Further analysis showed that the sizes of most proteins were distributed in the range of 10 to
242 200kDa, which meant reliable results (Figure 3E).

243 **The cardiac hypertrophy signaling pathway is negatively regulated in AF patients' left** 244 **atrium**

245 To confirm the KEGG enrichment analysis, we found the role of DEPs on several signaling
246 pathways especially cardiovascular disease signaling (Figure 4A). We extracted the information
247 solely about cardiovascular disease signaling and found 6 specific cardiovascular signaling

248 pathways, including cardiac hypertrophy signaling (Enhanced), the role of NFAT in cardiac
249 hypertrophy, endothelin-1 signaling, thrombin signaling, HIF1 α signaling and Cardiac
250 hypertrophy signaling were negatively regulated by the changed proteins (Figure 4B). Among
251 them, CACNA2D2, CACNB2 and MYL2 were get involved (Figure 4C).

252 **Hypertrophic and dilated cardiomyopathy KEGG pathways were identified in the AF** 253 **patients' cardiomyocyte**

254 To predict the possible roles of DEPs, the INGENUITY pathway analysis was conducted. As
255 shown in Figure 5A, 21 types of cardiovascular diseases were linked to DEPs when compared
256 AF with non-AF atrial tissues. The predictive p -value was far away less than 0.05. Among them,
257 abnormal morphology of the heart was associated with 20 changed proteins, abnormality of the
258 heart ventricle was connected with 13 changed proteins and hypertrophic cardiomyopathy was
259 related to 7 changed proteins. The enlarged left atrium was the outcome of mitral stenosis or
260 mitral regurgitation from concentric hypertrophy to eccentric hypertrophy in the development of
261 cardiac remodeling of rheumatic valvular heart disease (Figure 5B). A volcano plot showed the
262 decreased CACNA2D2, CACNB2, MYL2 and MAP6 are highly involved in the development of
263 these three morphological changes of the heart (Figure 5C). Further, KEGG enrichment analysis
264 indicated that these four down-regulated proteins were mainly enriched in the following two
265 pathways: calcium transport and myofibril assembly in cardiomyocytes (Figures 5D and 5E).

266 **Impact of Cldn5 knockdown on dilated cardiomyopathy pathway *in vivo***

267 The decreased expression of the targeted four DEPs mentioned above in AF patients'
268 cardiomyocytes was further confirmed by western blot (Figure 6A). Immuno-electron
269 microscopy for Cldn5 showed the morphology of mitochondria collapsed with decreased
270 immunogold-Cldn5 on them (Figure 6B). Similar results were verified in an in-vitro study where
271 Cldn5 was knocked down by shRNA AAV infection for 4 weeks in murine LV. Western blot
272 showed down-regulated protein levels of CACNA2D2, CACNB2, MYL2 and MAP6 after the
273 expression of Cldn5 was disturbed (Figure 6C). The disruption of mitochondrial morphology and
274 distribution as well as depletion of mitochondria were also observed in Cldn5 shRNA AAV-
275 infected myocardium (Figure 6D).

276 **Cldn5 knockdown decreases the mitochondrial density and mitochondrial membrane**
277 **potential *in vitro***

278 In vitro studies were conducted in HL-1 cells to assess the influence of Cldn5 on the protein
279 levels of CACNA2D2, CACNB2, MYL2 and MAP6 and observe the role of Cldn5 on
280 mitochondrial membrane potential. The four targeted proteins were all down-regulated by si-
281 Cldn5 transfection for 48 hours in the culture medium (Figures 7A and 7B). Decreased number
282 of mitochondria was also observed by Mitotracker staining under confocal microscopy (Figures
283 7C and 7D). We further detected significantly enhanced fluorescence of JC-1 monomers (green
284 color) after Cldn5 knockdown, which indicated mitochondrial membrane potential was
285 decreased (Figures 7E and 7F).

286 **Discussion**

287 Major findings.

288 Our study firstly demonstrates that reduced expression of Cldn5 in cardiac tissue along with
289 decreased CACNA2D2, CACNB2, MYL2 and MAP6 might induce disturbance of myofibrils
290 and microtubules as well as dysfunction of calcium transport, which leads to myocardial
291 excitation-contraction coupling disorder followed by atrial atrophy, dilation and AF. These
292 findings summarized in Fig. 8 broaden our comprehension of the effect of cell-cell adhesion on
293 arrhythmia.

294 Connexins and AF

295 The pathogenesis of AF is linked to gap junction remodeling of atrial tissue. Gap junctions are
296 communication structures while tight junctions serve the major functional purpose of providing a
297 “barrier” within the endothelial and epithelial membrane.¹⁴ Normal cardiac conduction requires
298 gap junction proteins like Cx30, Cx40, Cx43 and Cx45. Since they provide the syncytial
299 properties of the atrium and ventricle, changes in their expression and distribution may lead to
300 arrhythmias. For instance, Cx30 deficient mice had a faster mean daily heart rate than control
301 mice.¹⁵ Cx30.2 deficient mice also had shorter PQ intervals, elevated AV-nodal conduction
302 velocity and faster ventricular response rates compared to WT littermates.¹⁶ Cx40 and Cx43
303 downregulation in the atrium and ventricle of the rabbit’s hearts, respectively, have been thought

304 to enhance the susceptibility to atrial and ventricular tachycardia or fibrillation,^{17, 18} and the
305 heavy ion beam is reportedly promising in the treatment of arrhythmia by increasing the
306 expression of Cx40/43 in animal models.¹⁹ Additionally, clinical studies also confirmed severely
307 decreased Cx40 levels and reduced overlap with Cx43 in AF patients' atria.⁷ These lines of
308 evidence have demonstrated the critical role of Cxs in controlling the cardiac rhythm and cardiac
309 conduction, however, the function of the tight junction channel in the pathogenesis of AF is still
310 largely undefined.

311 Mechanisms of the causes of Cldn5 deficiency and AF

312 Cardiomyocyte's rod-shaped cell morphology is stabilized through specific and direct
313 interaction via the intercalated disk localized at the bipolar ends of the cardiomyocyte, while the
314 lateral cell surface is believed to interact with the extracellular matrix through receptors on the
315 costamere without physical contacts between proximate cardiomyocytes. Cldn5 is found
316 localized in the lateral membranes of cardiomyocytes and is decreased in a mouse model of
317 muscular dystrophy with cardiomyopathy.²⁰ Our previous study further found Cldn5 was
318 localized in both sarcolemma and mitochondria of cardiomyocytes and acted as a mitochondrial
319 dynamic regulator preventing mitochondrial fission and preventing the heart from ischemic
320 insult.¹³ However, the electrophysiological role of Cldn5 was still not fully investigated though
321 there was evidence linking tight junction protein to disturbed cardiac rhythm. It has been
322 reported that tight junction protein 1 (TJP1) cardiac-specific deletion transgenic mice developed
323 AV block along with decreased Cx40 expression and intercalated disc localization.²¹ Another
324 study showed that tight junction protein, coxsackievirus-adenovirus receptor (CAR), and heart-
325 specific inducible knockout impaired electrical conduction between the atrium and ventricle in
326 mice.²² In the present study, we hypothesized the decreased protein level of Cldn5 in AF patients
327 left atrium was linked to AF, therefore we used Cldn5 shRNA AAV infection to knockdown
328 cardiac Cldn5, and we found ST elevation, ventricular premature beat and AF in Cldn5 ventricle
329 knockdown mice. We also found the expression of Cx40/43 was not changed in western blot
330 after Cldn5 knock down (unpublished data). The implication of these novel findings is that
331 myocardial tight junction protein, Cldn5, maybe also crucial in maintaining normal
332 electrophysiology.

333 The mechanism underlying the pathogenesis of AF and the other cardiac rhythm disturbance
334 in mice after *Cldn5* knockdown in the left ventricle might be different from that of reduced
335 *Cldn5* in AF patients' left atrium though, we captured the common changes of molecules from
336 western blot analysis which showed the protein levels of *CACNA2D2*, *CACNB2*, *MAP6* and
337 *MYL2* were significantly downregulated. Actually, *CACNA2D2* serves in vivo as a component
338 of a P/Q-type calcium channel, a functional auxiliary subunit of voltage-gated Ca^{2+} channels, and
339 is indispensable for central nervous system function.²³ Evidence showed that inhibition or
340 knockdown of *CACNA2D2* could induce arrhythmias in rat ischemic hearts.²⁴ Moreover, a loss-
341 of-function mutation in another L-type calcium channel subunit gene *CACNB2* also has been
342 reported to cause a short QT syndrome subtype.²⁵ A missense variant in *CACNB2* is also
343 associated with ventricular fibrillation.²⁶ Therefore, the downregulated expression of
344 *CACNA2D2* and *CACNB2* in AF patients' cardiomyocytes and in *Cldn5* knockdown murine
345 cardiomyocytes in the present study suggest a novel role of *Cldn5* in modulating calcium
346 transport via voltage-gated Ca^{2+} channels.

347 The reduction of protein level of *Cldn5* is observed in human heart samples from end-stage
348 cardiomyopathy,¹¹ and *Cldn5* mRNA and protein levels are also specifically reduced in the heart
349 from a mouse model of muscular dystrophy with cardiomyopathy induced by
350 utrophin/dystrophin double knockout.²⁰ On the contrary, the over-expression of *Cldn5* via
351 adeno-associated virus (AAV) in these double-knockout mice could prevent the development of
352 cardiomyopathy and improve cardiac damage.²⁷ Although the connection between *Cldn5* and
353 dystrophy in cardiomyopathy or muscular dystrophy is inconclusive, the relation between
354 decreased *Cldn5* and cardiomyopathy is apparent. Here we show that significant cardiac myocyte
355 atrophy is common in cardiomyocytes from AF patients' left atrial appendage and from mouse
356 left ventricle after *Cldn5* knockdown. These observations are consistent with the data above
357 suggesting the role of *Cldn5* in maintaining the cellular morphology of cardiomyocytes. The
358 mechanism underlying this phenomenon might be associated with decreased *MAP6* and *MYL2*
359 predicted by proteomic analysis and confirmed by western blot. Since the evidence showed that
360 deletion of the *MAP6* resulted in skeletal muscle atrophy and weakness in mice,²⁸ and mutation
361 in *MYL2* gene was identified in hypertrophic cardiomyopathy (HCM),^{29,30} we believe that the
362 deficiency of these two proteins after *Cldn5* depletion is associated with cardiac myocyte atrophy
363 in the current study.

364 Furthermore, in our cellular study knockdown Cldn5 in HL-1 cells, we also observed similar
365 results from the in vivo study. Mitochondrial dysfunction might be the key process underlying
366 Cldn5 deficiency-induced arrhythmia since mitochondrial number and membrane potential were
367 decreased after Cldn5 knockdown. These results were consistent with our previous observation
368 that mitochondrial fission was enhanced in cardiomyocytes post hypoxia-reoxygenation when
369 Cldn5 was knocked down by siRNA.¹³ Furthermore, Cldn5 overexpression attenuated
370 myocardial oxidative stress and mitochondrial dysfunction in mice subjected to myocardial
371 ischemia reperfusion injury.³¹ Together these findings suggest that mitochondrial dysfunction
372 induced by the downregulation of Cldn5 along with the significant decrease of CACNA2D2,
373 CACNB2, MAP6 and MYL2 contributed to calcium transport disturbance and myofibrils and
374 microtubules disturbance, leading to myocardial excitation-contraction coupling disorder
375 followed by cardiac myocyte atrophy and fibrillation (Figure 8).

376 Study limitations

377 Although the expression of Cldn5 was decreased in the left atrial appendages in patients with
378 AF, Cldn5 shRNA AAV was injected into the myocardium of the anterior left ventricle rather
379 than the left atrium in this study, suggesting the uncertainty of the areas of Cldn5 expression of
380 the role of AF. Secondly, due to the embryo-lethal, this was a study performed without a Cldn5
381 gene knockout mouse. An inducible cardiomyocyte-specific Cldn5 deletion mouse (Cldn5^{fl/fl};
382 Myh6^{Cre/Esr1*}) will be used in future studies. Moreover, the mechanisms by which Cldn5
383 knockdown leads to the downregulation of CACNA2D2, CACNB2, MYL2 and MAP6 are not
384 investigated. The interactions between Cldn5 and these four proteins should be considered due to
385 the fact that in failing heart, Cldn5 in cardiomyocytes is reduced and Ephrin-B1 localization is
386 altered,¹² which hinting that Cldn5 may be required for stabilizing the localization of the other
387 receptors or proteins.

388 Conclusions

389 This is the first clinical study to show the role of Cldn5 on cardiac rhythm and cardiac
390 hypertrophy. The enlargement of LA in Af patients is accompanied by cardiac atrophy and
391 decreased Cldn5 meanwhile cardiac Cldn5 deficiency leads to disturbance of cardiac rhythm and
392 myocyte atrophy. Cell culture findings show decreased mitochondrial numbers and membrane

393 potential. Proteomic study and western blots results demonstrate the detrimental effect of Cldn5
394 deficiency is associated with the downregulation of CACNA2D2, CACNB2, MYL2 and MAP6.
395 These findings may be considered for the development of promising cardioprotective
396 therapeutics based on claudin-5 to maintain healthy cardiac rhythm and morphology.

549 deviation (RSD) of the samples. (C) Statistical analysis of differentially expressed proteins
550 (DEPs). (D) A heatmap with hierarchical clustering of DEPs. (E) The distribution of the
551 molecular size of the identified proteins.

552 **Fig. 4 INGENUITY pathway analysis (IPA) results.** (A) Bubble chart of metabolic pathway
553 and signal pathway associated with differentially expressed proteins (DEPs). Cardiovascular
554 signaling is marked by the red font. (B) Bubble chart of cardiovascular signaling. (C) Venn
555 diagram demonstrating the number of quantified proteins from the cardiac hypertrophy signaling.

556 **Fig. 5 AF patients' left atrial appendages proteomics exhibits a distinct profile for**
557 **abnormal heart ventricles.** (A) Cardiovascular disease analysis of DAPs. (B) Diagram
558 indicating the transition from hypertrophic cardiomyopathy to dilated cardiomyopathy. (C)
559 Volcano plot of DEPs. Red dots indicate significantly up-regulated proteins, blue dots indicate
560 significant down-regulated proteins and gray dots indicate proteins without differences. Among
561 blue dots, CACNA2D2, CACNB2, MYL2 and MAP6 were highly associated with hypertrophic
562 cardiomyopathy or dilated cardiomyopathy. (D and E) KEGG enrichment analysis of DEPs
563 indicating CACNA2D2, CACNB2, MYL2 and MAP6 were functioned as calcium transport and
564 myofibril assembly. And down-regulation of these proteins will lead to dilated cardiomyopathy.

565 **Fig. 6 Cldn5 knockdown on dilated cardiomyopathy pathway *in vivo*.** (A and B) The western
566 blot and quantitative analysis of the Cldn5, CACNA2D2, CACNB2, MYL2 and MAP6 in AF
567 and non-AF left atrial appendages. (C) Representative immunogold-Cldn5 and mitochondrial
568 morphology images were observed under transmission electron microscopy (TEM). Scale
569 bar=1 μ m. (D) Quantitative analysis of immunogold-Cldn5. (E and F) The western blot and
570 quantitative analysis of the Cldn5, CACNA2D2, CACNB2, MYL2 and MAP6 in the left
571 ventricles of Cldn5 shRNA AAV and AAV NC injected mice. (G) Representative images of
572 mitochondrial morphology under TEM. Scale bar=1 μ m. (H) Quantitative analysis of
573 mitochondrial number in different groups. * $P < 0.05$ vs. AAV NC; n = 5 in each group.

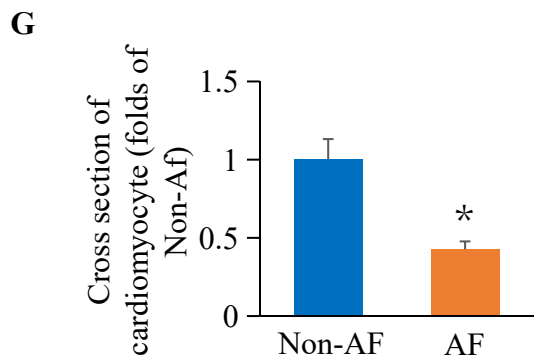

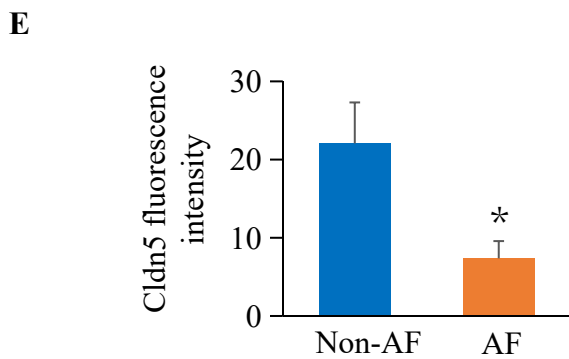

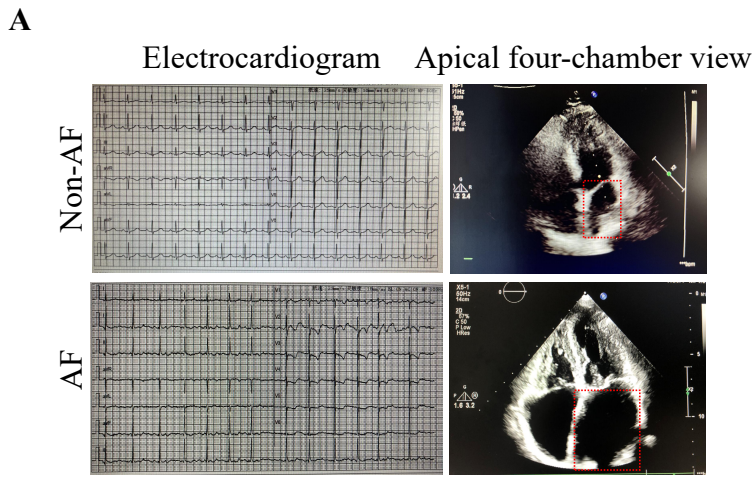

574 **Fig. 7 Cldn5 knockdown on the mitochondrial number and membrane potential *in vitro*.** (A
575 and B) The western blot and quantitative analysis of the Cldn5, CACNA2D2, CACNB2, MYL2
576 and MAP6 in HL-1 cells after si-Cldn5 transfection for 48 hours. Si-NC is used as the control
577 siRNA. (C) Representative images of mitochondria in HL-1 cells stained with Mitotracker Green.

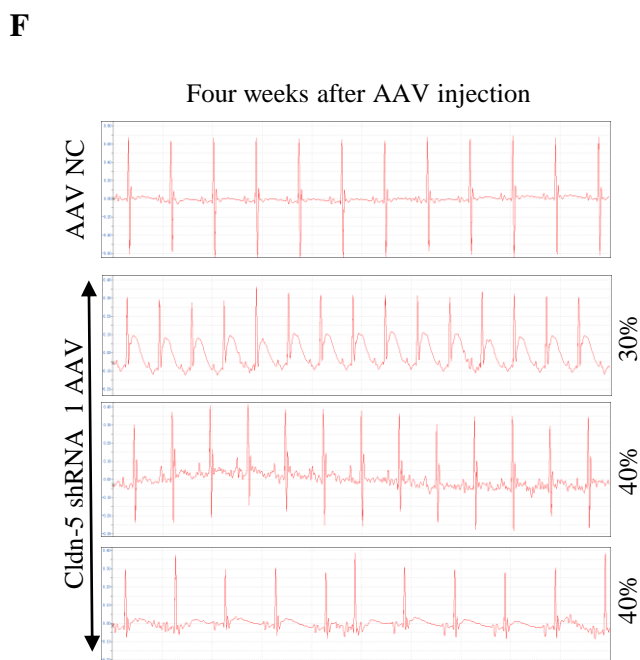

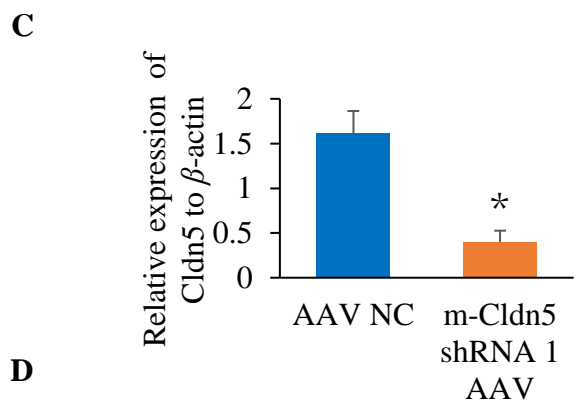

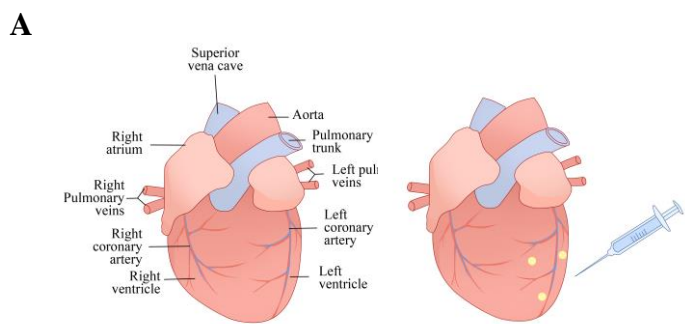

578 DAPI is used to stain the nucleus. (D) Quantitative analysis of Mitotracker fluorescence intensity.
579 Scale bar=100 μ m. (E) Mitochondrial membrane potential was analyzed by JC-1 staining. Scale
580 bar=100 μ m. (F) Quantitative analysis of the fluorescence intensity ratio between the red
581 aggregates and green monomer fluorescence. * $P < 0.05$ vs. Si-NC; n = 5 in each group.

582 **Fig. 8 Diagram of claudin-5-mediated signaling.**

583 Cldn5 deficiency decreases the expression of CACNA2D2 and CACNB2, leading to calcium
584 transport disturbance. Mitochondrial membrane and membrane potential were decreased after
585 Cldn5 knockdown. Cldn5 deficiency also decreases the expression of MYL2 and MAP6 which
586 are responsible for the disturbance of myofibril assembly and microtubule stabilization. All these
587 effects lead to myocardial excitation-contraction coupling disorder followed by cardiac myocyte
588 atrophy and atrial fibrillation.
