19 **Abstract**

20 For breast and ovarian cancer risk assessment in the isolated populations of the Northern Isles of Orkney
21 and Shetland (in Scotland, UK) and their diasporas, quantifying genetically drifted *BRCA1* and *BRCA2*
22 pathogenic variants is important. Two actionable variants in these genes have reached much higher
23 frequencies than in cosmopolitan UK populations. Here, we report a *BRCA2* splice acceptor variant, c.517-
24 2A>G, found in breast and ovarian cancer families from Shetland. We investigated the frequency and
25 origin of this variant in a population-based research cohort of people of Shetland ancestry, VIKING I. The
26 variant segregates with female breast and ovarian cancer in diagnosed cases and is classified as
27 pathogenic. Exome sequence data from 2,108 participants with three or more Shetlandic grandparents in
28 VIKING I was used to estimate the population prevalence of c.517-2A>G in Shetlanders. Nine VIKING I
29 research volunteers carry this variant, on a shared haplotype (carrier frequency 0.4%). This frequency is
30 ~130-fold higher than in UK Biobank, where the small group of carriers has a different haplotype. Records
31 of birth, marriage and death indicate genealogical linkage of VIKING I carriers to a founder from the Isle of
32 Whalsay, Shetland, similar to our observations for the *BRCA1* founder variant from Westray, Orkney. In
33 total, 93.5% of pathogenic BRCA variant carriers in Northern Isles exomes are accounted for by these two
34 drifted variants. We thus provide the scientific evidence of an opportunity for screening people of
35 Orcadian and Shetlandic origins for each drifted pathogenic variant, particularly women with Westray or
36 Whalsay ancestry.

40 **Introduction**

41 Pathogenic variants in *BRCA1* and *BRCA2* confer a high lifetime risk of breast, ovarian and, for *BRCA2*,
42 male breast and prostate cancer (1-3). Genetic testing for disease-associated variants in these genes is
43 increasingly available as part of routine clinical care, to enable not only early detection and risk reduction,
44 but also to guide cancer treatment decisions. The genes are considered “tier 1” genes by the Centers for
45 Disease Control and Prevention Office of Public Health Genomics, on the basis that early detection of
46 pathogenic variants will have a positive effect on public health. Predictive testing of unaffected family
47 members is well established, with female pre-symptomatic carriers of pathogenic variants being offered
48 risk-reducing salpingo-oophorectomy and mastectomy, and early onset annual MRI breast screening.
49 Pathogenic variants in *BRCA2* also increase risk of prostate cancer and male breast cancer (4), with male
50 pre-symptomatic carriers typically being offered prostate-specific antigen screening in the NHS.
51 Compellingly, the Icelandic p.Asn257LysfsTer17 founder variant in *BRCA2* (previously termed 999del5 (5))
52 was associated with a shorter lifespan for both female carriers (effect of the variant, -9.3 years) and male
53 carriers (effect of the variant, -4.6 years) (6).

54 In isolate populations, a pathogenic variant present in a founding or early member can become more
55 frequent in later generations. Pathogenic variants in *BRCA1* and *BRCA2* that have drifted up in frequency
56 due to founder events have been described in many isolate and founder communities worldwide, notably
57 Ashkenazi and Sephardi Jews (7, 8), and Icelanders (5), as well as in larger populations (9).

58 The Northern Isles of Scotland – the Orkney and Shetland archipelagos - contain the most isolated of all
59 British and Irish populations, with the highest degree of Norse admixture. The genome-wide
60 distinctiveness revealed at common variants (10) is also reflected in the spectrum of rare and ultra-rare
61 variation: many such variants are enriched in the Shetlandic population (11). This pervasive genetic drift
62 also influences variants of clinical importance. Examples in the Northern Isles include a pathogenic *BRCA1*
63 founder variant that has drifted to high frequency in Orkney (12), and an actionable *KCNH2* Long QT
64 Syndrome variant in Shetland (13). Here, we survey the landscape of pathogenic *BRCA1*, (MIM#113705)
65 *BRCA2* (MIM#600185) and other breast cancer risk variants in the Northern Isles of Scotland.

66 The NHS Grampian clinical genetics team initially observed the *BRCA2* splice acceptor variant, c.517-2A>G,
67 in breast and ovarian cancer cases from Shetland. The interpretation that this base substitution is a
68 pathogenic variant was demonstrated independently by multifactorial likelihood quantitative analysis
69 (definitely pathogenic, posterior probability 0.9994), together with co-segregation and tumour pathology
70 (14). The c.517-2A>G variant (also known as IVS6-2A>G) has been reported in multiple individuals affected
71 with Hereditary Breast and Ovarian Cancer worldwide, and is classed as pathogenic (reviewed by an
72 expert panel) in ClinVar (15), accession number VCV000051801. This *BRCA2* variant lies in a canonical
73 splice acceptor site and is predicted using a range of tools to affect mRNA splicing, resulting in a
74 significantly altered protein due to exon skipping (16). Experimental evidence *in vitro* supports these
75 bioinformatic predictions (16, 17).

76 Viking Genes (viking.ed.ac.uk) comprises three cohort studies aiming to explore the genetic causes of
77 disease – the Orkney Complex Disease Study (ORCADES), VIKING I and VIKING II/III. VIKING I contains a
78 rich data resource of more than 2,000 deeply phenotyped and exome-sequenced research subjects with
79 three or four grandparents from Shetland, whereas ORCADES is a similar-sized cohort of participants from
80 Orkney. Most recently, VIKING II/III is a worldwide cohort of 6,000 people, recruited online, with ancestry
81 from the Northern or Western Isles of Scotland (18). The UK Biobank is a cosmopolitan biomedical
82 database containing genetic, lifestyle and health information from half a million participants in the UK
83 (19). Here, we report the ascertainment of the *BRCA2* pathogenic variant c.517-2A>G in both clinical care
84 in cancer families, and research volunteers, from Shetland. We investigate relatedness of the variant
85 carriers in Shetland using genealogy, infer origins, compare haplotypes in VIKING I and UK Biobank carrier
86 participants and estimate population frequencies of pathogenic BRCA variants in Scottish island founder
87 populations both individually and collectively.

88

89 **Materials and Methods**

90 *Genotyping*

91 DNA from all VIKING I participants was used for genome-wide genotyping on the GSA BeadChip (Illumina)
92 at the Regeneron Genetics Center. Monomorphic genotypes and genotypes with more than 2% of

93 missingness and Hardy-Weinberg equilibrium (HWE) $p < 10^{-6}$ were removed, as well as individuals with
94 more than 3% of missingness. Details of genotyping, sample and variant quality control of UK Biobank
95 genotyping data are described in Bycroft *et al* (20).

96 *DNA Sequencing and Annotation*

97 The fully quality-controlled exome sequence data set of 2,108 VIKING I sequences (843 male and 1,265
98 female participants) passed all genotype quality control thresholds as described previously for the exomes
99 in the ORCADES cohort (12). The data was prepared at the Regeneron Genetics Center, following the
100 process detailed for UK Biobank (21). Details of the quality control of whole exome sequencing on the
101 200,000 participants from the UK Biobank are described in Backman *et al* (22). For Viking Genes, exonic
102 variants passing QC in *BRCA1*, *BRCA2* and other cancer risk genes were filtered against ClinVar (15)
103 (accession date 28th March 2023) and Pathogenic/Likely Pathogenic variants were retained, irrespective
104 of star status. Pre-designed primers (Hs00585575, Thermo Fisher Scientific) were used to generate a PCR
105 fragment of 268 base pairs from genomic DNA for analysis. The *BRCA2* c.517-2A>G, rs81002858 variant
106 was confirmed in VIKING I carriers by Sanger sequencing on an Applied Biosystems 3730xl Genetic
107 Analyser. All nine heterozygous variant calls from the VIKING I exome dataset were verified.

108 *Haplotype analysis*

109 The VIKING I array genotype data were phased using Shapeit2 v2r837 (23), with the duoHMM option that
110 uses the family-based nature of the data (24). Prior to phasing, the array genotype data were lifted over
111 from the genome build GRCh38 to GRCh37 using LiftOver, followed by quality control against the TOPMED
112 reference panel with Rayner's HRC-1000G-check-bim (v4.2.13) script that was downloaded from
113 <https://www.well.ox.ac.uk/~wrayner/tools/>. UK Biobank data were interrogated to ascertain the
114 frequency of the variant of interest. Details of phasing of UK Biobank genotyping data have been
115 described (20). Then, the phased genotypes were used to determine a shared haplotype around c.517-
116 2A>G using the fine method described previously (13). All methods were performed using R 4.0.2 (R Core
117 Team 2020 <https://www.R-project.org/>). Haplotypes were defined with custom-built in-house scripts in R.
118 Data handling was performed using data.table and tidyverse R packages. Plots were generated using
119 ggplot2.

120 A single variant-based haplotype search was performed to determine the haplotype length between the
121 different VIKING I carrier kindreds, and with the UK Biobank carrier individuals, using a stepwise approach.
122 Using phased genotype data, starting from the rs81002858 rare variant, one SNP at a time was added to
123 define a haplotype. The procedure was repeated until haplotypes of two individuals (both known carriers)
124 no longer matched, both upstream and downstream of the rare variant, providing variant-level resolution
125 of the haplotype length. The procedure was repeated for all pairs of individuals identified as carriers based
126 on the exome sequencing data, both in the VIKING I and UK Biobank datasets. The shortest shared
127 haplotype from VIKING I was then merged with the shortest shared haplotype from the UK Biobank, to
128 compare whether the haplotypes match.

129 *EHR Data Linkage in VIKING I*

130 NHS routine datasets linked to VIKING I participants in July 2021, including the Scottish Cancer Registry
131 SMR06, were accessed using a secure process, as described previously (12).

132

133 **Results**

134 *Clinical ascertainment of the BRCA2 c.517-2A>G variant*

135 Eleven women from four Shetland families presenting with *BRCA2*-related cancers were found to have the
136 *BRCA2* c.517-2A>G variant, as part of routine clinical care. The family branches share some common
137 surnames, but the branches could not be genealogically linked. Two of the branches overlap
138 genealogically with two VIKING I families with the same variant. To date, five of these 11 clinically
139 ascertained carriers have had breast or ovarian cancer. Not all would have met the criteria for genetic
140 testing in the mainstream NHS setting (see Supplementary Methods), without the context of the wider
141 family health history.

142 *Population frequencies of the BRCA2 c.517-2A>G variant*

143 Data from 2,108 VIKING I participants passed all exome sequence and genotype quality control thresholds.
144 There are nine heterozygous carriers of the *BRCA2* c.517-2A>G variant in the VIKING I exome dataset, of
145 whom six are female. The Genome Aggregation Database (gnomAD v4.0) (25), containing over half a
146 million exomes from unrelated individuals, has 14 heterozygous carriers of the c.517-2A>G variant (Table

147 1). Consistent with this rarity, the variant is not observed in 2,090 participants in ORCADES (12). In good
148 agreement with gnomAD, 458,838 whole genome sequences from the UK Biobank (26) contain fifteen
149 instances (Table 1).

150

151 We have access to exome sequence data from 200,000 individuals from UK Biobank, six of whom carry the
152 variant. These six were born and live in England, mostly in Yorkshire. Variant carriers are also reported in a
153 national UK repository of variants in cancer predisposition genes in cancer patients, CanVar-UK (27). There
154 are 35 carriers in this dataset (Table 1), five of whom are recorded as of non-European heritage. The
155 variant was also noted in one participant in a study of Japanese women with breast cancer (28).

156 *Origin of the c.517-2A>G variant in Shetland*

157 Three out of nine of the VIKING I variant carriers had all four grandparents born in the Isle of Whalsay, one
158 of the North Isles of Shetland, and five of them had at least one Whalsay grandparent. Of all 36
159 grandparents of the carriers, 14 (39%) were from Whalsay, with most of the remainder coming from other
160 parishes or isles of Shetland (Figure 1). The *BRCA2* pathogenic variant c.517-2A>G in Shetland thus shows
161 evidence of a founder from the parish of Whalsay.

162

163 Church records and data from the Scottish register of births, marriages and deaths traced six of the nine
164 research carriers to lineages with an origin in a couple born over 200 years ago on the island of Whalsay,
165 in the Shetland Isles (Figure 2). A further carrier descends from the same ancestral surname in the same
166 isle, potentially linking into the pedigree ~300 years ago (not shown), but the genealogical records do not
167 survive to prove the link. The c.517-2A>G families in the research cohort can thus be traced back to this
168 family, apart from two closely related carriers who have no genealogical links and no known ancestors
169 from Whalsay. This “Family B” is not shown in Figure 2, and is probably the result of an ancestral non-
170 paternity event, given they share a haplotype with the main kindred and its outlier (see below).

171

172 *c.517-2A>G carriers in VIKING I and UK Biobank do not share a common haplotype*

173 All nine heterozygous c.517-2A>G carriers in VIKING I share the same haplotype around the variant locus,
174 with a minimum length of 3.6 Mb (Figure 3). Analysis of haplotypes in the genotype data from six UK
175 Biobank participants carrying the variant showed that all but one share a minimum ~0.7 Mb haplotype
176 around the variant. However, this was different to the Whalsay haplotype from VIKING I, and is noticeably
177 shorter: on average 1.4 Mb are shared vs. 9 Mb among the Shetlanders (excluding relatives closer than
178 fifth degree). The final UK Biobank carrier shares neither of these haplotypes.

179

180 *Penetrance of BRCA2 c.517-2A>G*

181 Linkage to routine NHS data in the electronic health record (EHR) provides a longitudinal component to
182 the Viking Genes research cohorts, and affords the opportunity for unbiased penetrance estimates. All
183 nine c.517-2A>G carriers gave consent for EHR linkage, and the mean age of the six female carriers at time
184 of recruitment to VIKING I (baseline in 2013-2015) was 52. Analysis of the NHS cancer registry (SMR06)
185 dataset shows that one of the female c.517-2A>G carrier participants has a diagnosis of breast cancer, and
186 one of ovarian cancer. None of the other seven carriers (four females and three males) had any cancer
187 code recorded, or codes in the hospital admissions (SMR01) dataset for relevant risk-reducing surgery,
188 and all nine were alive in 2021. Volunteers also complete study questionnaire sections on family history of
189 disease, and this reveals that two obligate carriers – parents of participants, through which they link to
190 other carriers – were affected with cancer. One of these cancers (in a father) was non-Hodgkin's
191 lymphoma, for which there is some evidence of association with pathogenic variants in *BRCA2* (29).

192 *The landscape of BRCA1 and BRCA2 pathogenic variants in the Northern Isles*

193 Apart from the two founder variants (*BRCA1* c.5207T>C; *BRCA2* c.517-2A>G), in our ~4,200-person
194 Northern Isles sample, only four other actionable BRCA variants are observed, all of them singletons in
195 *BRCA2* (Supplementary Table 1). Two of these were inherited by participants from non-Northern Isles
196 parents, meaning that 93.5% of actionable BRCA variant carriers in Northern Isles genomes are accounted
197 for by the two drifted variants. One of the singletons inherited from outside the Isles (from a NE Scottish
198 Mainland-born parent) was the NE Scottish founder variant *BRCA2* c.6275_6276del p.Leu2092fs (also

199 called 6503delTT; rs11571658 (30)). The other noted West Central Scottish founder variant, *BRCA1*
200 2800delIAA (31), was absent from our cohorts.

201 *Allele frequencies of founder BRCA variants*

202 To explore further how common the drifted c.517-2A>G *BRCA2* variant is across Shetland, we filtered our
203 population for people with four grandparents, and therefore their entire genome, from the Isle of
204 Whalsay. While there will be large confidence intervals, the point estimate of the carrier frequency is
205 2.3%, or one in 43 people from this isle, five-fold higher than in a general sample of Shetlanders, where
206 the carrier frequency is 1/234 (Table 2). For comparison, we have also analysed data from Orkney for the
207 drifted *BRCA1* c.5207T>C variant, filtering for people with one or more grandparents from the Isle of
208 Westray, Orkney. The genetic drift is more extreme, with a carrier frequency estimate of 5.2% or 1 in 19
209 Westray genome equivalents, again five-fold higher than in a general sample of Orcadians. These
210 otherwise rare pathogenic alleles are therefore 700-2300 times more common in these isles than in the
211 general UK Biobank population (Table 2). For added context, numbers are also given in Table 2 for the
212 well-known Icelandic *BRCA2* (6) and Ashkenazi Jewish *BRCA1* and *BRCA2* pathogenic alleles (7), with
213 carrier frequencies between 1 in 138 in Iceland and 1 in 41 for the combination of three variants in the
214 Ashkenazi community.

215
216 The frequency estimates of BRCA variants in the Northern Isles of Scotland are in total somewhat higher
217 than among women in the UK in general. For example, 1/293 women in UK Biobank are carriers of
218 pathogenic / likely pathogenic (with at least 2 star status in ClinVar) or predicted protein-truncating
219 variants in *BRCA1/2* (32). Hence, the proportion carrying a potentially damaging BRCA variant in Orkney
220 (1/105) is more than twice that elsewhere in the UK. However, as shown in Table 2, it is when the
221 individual isle of origin is considered that the carrier frequencies rise an order of magnitude (e.g. 1/43 in
222 Whalsay, 1/19 in Westray), similar to the 1/41 observed for Ashkenazi Jews (three founder variants).

223 *Other breast cancer susceptibility genes*

224 Variants in the ataxia telangiectasia mutated gene *ATM* can increase the risk of breast cancer, though the
225 gene is not on the ACMG v3.2 list of recommendations for reporting secondary findings in clinical exome

226 and genome sequencing (33). A pathogenic coding variant in *ATM* (c.7271T>G p.Val2424Gly; rs28904921,
227 ClinVar VCV000003023) was described in an Orkney pedigree in 1998 (34), the “core” family. The variant is
228 rare but widespread globally, and case-control studies indicate it is strongly associated ($OR \sim 10$) with
229 breast cancer (35, 36). In the ORCADES research cohort, we recovered the same previously reported
230 family (34). Beyond the previously reported three heterozygotes and three homozygotes, we identified
231 one further heterozygote closely related to this family.

232 Two further *ATM* p.Val2424Gly carriers were found, one is a seventh degree relative of the core family. In
233 total there are 6 alleles out of 4,180 sequenced in ORCADES = 0.14%. For comparison, in the UK Biobank
234 there are 91 alleles out of 917,638 European alleles sequenced = 0.0099%, thus there is a moderate uplift
235 in Orkney (~15-fold). We know from questionnaire data that a large number of first and second-degree
236 relatives of the carriers in the core family are alive but not in the ORCADES study, some of whom may
237 have volunteered to join the online study VIKING II (18). This may allow a better delineation of the size of
238 the kindred, and more accurate estimation of the frequency and any impact of the variant on breast
239 cancer risk in the Northern Isles of Scotland.

240 The relatively common loss-of-function c.1100del variant in *CHEK2* (rs555607708, ClinVar VCV000128042)
241 imparts a moderate risk of breast and prostate cancer, even in individuals unselected for family history
242 (37, 38). We observed only four heterozygous carriers of this variant, two from ORCADES and two from
243 VIKING I, giving an estimated minor allele frequency of 0.048% in the Northern Isles. This is five-fold lower
244 than the 0.24% seen in UK Biobank. It is notable that three of these four carriers in the Viking Genes
245 cohorts derive half their genomes from Lowland Scotland, and in one individual we know the allele must
246 have originated from the Scottish Mainland parent. This suggests c.1100del was rare-to-absent in the pre-
247 WWII Northern Isles gene pool (due to genetic drift), but appears today due to post-WWII immigration
248 from the rest of the British Isles. Like *ATM*, *CHEK2* is not on the ACMG3.2 gene list of recommendations
249 for reporting incidental findings (33), but discussions related to the inclusion of further moderate
250 penetrance breast cancer genes, including both *ATM* and *CHEK2*, are ongoing (39); both of the above
251 variants are tested clinically in the UK, according to set guidelines (40).

252 No pathogenic exonic variants in other genes which confer an increased risk of breast cancer were
253 discovered: *TP53*, *PALB2*, *STK11*, *PTEN* – suggesting these are also essentially absent from the Northern
254 Isles gene pools. Moreover, none of the *BRCA2* c.517-2A>G carriers in VIKING I also carry known
255 pathogenic exonic variants in the cancer susceptibility genes *APC*, *BRCA1*, *RET*, *MAX*, *TMEM127*, *BMPR1A*,
256 *SMAD4*, *MLH1*, *MSH2*, *MSH6*, *PMS2*, *MEN1*, *MUTYH*, *NF2*, *SDHD*, *SDHAF2*, *SDHC*, *SDHB*, *RB1*, *VHL* or *WT1*.
257 In the Northern Isles, the effects of random genetic drift over the centuries have thus simplified the
258 landscape of highly penetrant variants of large effect, such that two variants account for almost all of the
259 risk arising from rare pathogenic hereditary breast and ovarian cancer variants, while the impact of all
260 others is negligible. Clearly, high penetrance genes contribute only a proportion of genetic cancer risk,
261 whereas common low penetrance variants identified through genome-wide association studies explain a
262 further component, as of course do environmental exposures.

263

264 Discussion

265 We recurrently identified the pathogenic *BRCA2* variant c.517-2A>G in the population of Shetland, both in
266 clinical practice and in a population cohort. The variant is found in ~0.4% of Shetlanders. All carriers in the
267 Shetland cohort VIKING I share the same haplotype background, which is distinct from that observed in
268 English UK Biobank carriers, pointing to recurrent mutation at the site. Genealogical analysis suggests the
269 variant is likely to have originated or arrived in a founder individual from Whalsay, Shetland, over 300
270 years ago. The presence of the same variant in a Japanese study, and in five non-white individuals in
271 CanVar, provides further evidence that this variant has arisen more than once worldwide.

272 Individuals not ascertained by cascade testing of relatives from the clinical pedigrees were identified in
273 the population-based sample. In previous work on the *KCNH2* variant p.Gly584Ser (13), which increases
274 risk of long QT syndrome, and on *BRCA1* p.Val1736Ala (12), we similarly identified carriers in our Northern
275 Isles research populations who could not have been ascertained from family-based cascade testing. This
276 highlights the value of research cohorts in uncovering rare clinical variants, which may in turn help
277 planning and implementation of genetic services. Our online cohort study, VIKING II, which has recruited
278 volunteers with Northern Isles grandparents irrespective of domicile (18), has highlighted scientifically for

279 the first time the extent of emigration. Significant Northern Isles diasporas are found in mainland
280 Scotland, former British colonies, particularly New Zealand, Canada and Australia, and also in England, all
281 locations where these alleles are therefore likely to be important for some families.

282 We show that the frequency estimates of pathogenic BRCA alleles in Orkney and Shetland are somewhat
283 higher than those for women living in other areas of the UK. We have also demonstrated that variation in
284 *ATM* and *CHEK2* does not contribute significantly to breast cancer in Orcadians. However, the overall
285 numbers affected by high penetrance variants will be low, given the modest population sizes. In the most
286 recent census for which data is available (2011), the population of Whalsay was 1,061 and of Westray,
287 588, while Shetland and Orkney had 23,167 and 21,279 inhabitants, respectively. The size of the extensive
288 diasporas is unknown. Given the combined population of over 64,000 in 1861 and the estimated number
289 of living descendants that would arise in line with European population growth rates in this period, we
290 speculate that the diasporas number in the hundreds of thousands, although the great majority will have
291 inherited only a fraction of their genomes from Northern Isles ancestors. Ongoing isolate breakdown, due
292 to continued immigration to the isles, but also increased within-archipelago migration and mixing, are
293 expected to similarly result in dilution of these high Northern Isles frequencies over time.

294 High penetrance *BRCA1* and *BRCA2* founder pathogenic variants have been described in several
295 populations such as the Ashkenazim, Icelanders, Poles, Norwegians and others (8). Testing for these
296 variants is increasingly well established in both clinical (<https://www.nhsjewishbrcaprogramme.org.uk/>)
297 and research (41) contexts and cost-effectiveness has been demonstrated in a number of settings. A
298 recent opinion paper addresses the routine failure to identify many monogenic cases of common diseases,
299 including breast and ovarian cancer, in clinical settings (42). It aims to focus attention on universal genetic
300 testing in common diseases for which the recommended clinical management of patients with monogenic
301 forms of disease diverges from standard management, and has evidence for improved outcomes. In a
302 step towards this, all women with a diagnosis of a high-grade serous ovarian carcinoma in Scotland
303 (https://www.sign.ac.uk/media/2010/sign135_oct2022.pdf) and Wales, UK, are now tested for
304 pathogenic *BRCA* variants, without the need for any family history (43, 44). Furthermore, those with
305 breast cancer under the age of 40, and triple negative breast cancer under 60, regardless of family history,

306 are widely tested in the UK (Supplementary Methods). However, the challenges of potential reduced
307 penetrance in those without a known family history, and cost, have generally limited adoption of
308 asymptomatic *BRCA1* and *BRCA2* screening.

309 Homozygosity for pathogenic *BRCA2* variants causes a rare inherited form of bone marrow-associated
310 acute myeloid leukaemia, solid tumours and developmental anomalies termed Fanconi anaemia. We
311 estimate that the frequency of Fanconi anaemia in people with Whalsay grandparents could be as high as
312 1/10,000, considerably higher than the average for Europe of 4-7 per million (45). We propose that
313 awareness raising of this unlikely possibility in clinicians serving this population is important.

314 Single fragment Sanger sequencing for well characterised founder variants is considerably cheaper than
315 panel, whole exome or whole genome testing. Thus, testing efficiency would be likely to be considerably
316 higher in the Northern Isles of Scotland and their diaspora, as we have shown that ~93% of all actionable
317 variants in *BRCA* genes are accounted for by only two drifted variants. Furthermore, negligible numbers of
318 variants are segregating at other breast cancer risk genes. This is in sharp contrast with the 424 different
319 pathogenic or loss-of-function *BRCA1/BRCA2* variants found in UK Biobank females, where 369 variants
320 account for 93% of all actionable variants (*pers. comm.* L. Jackson, University of Exeter, from analysis of
321 pathogenic variants as described in (32)). This considerable simplification of the gene pool in genetic
322 isolates, predicted to be an important factor in gene mapping study designs (46), may in fact be more
323 critical when considering genomic medicine screening in these populations. There is a case for offering all
324 Orcadian and Shetlandic women testing for the relevant drifted pathogenic *BRCA* variant, particularly
325 those with Westray or Whalsay ancestry. A pilot of self-administered saliva-based testing is underway for
326 the *BRCA1* variant in Westray. Given current fiscal constraints and the somewhat lower frequency of the
327 Whalsay variant, the immediate recommendation is that testing for *BRCA2* c.517-2A>G should be offered
328 to those of Whalsay ancestry with a first-degree relative with breast or ovarian cancer, and, to those with
329 an affected second degree relative connected through an unaffected male.

330 Currently, the consent framework of most research cohorts – including UK Biobank – does not allow the
331 return of results about carrier status of actionable variants (21). However, participants in such studies
332 often wish to receive results, particularly about “actionable” findings. This has stimulated publication of

333 an international policy for returning genomic research results (47), and a practical checklist for return of
334 results from genomic research in the European context (48). Others also recommend the return of results
335 following detection of hereditary breast and ovarian cancer risk to adult population-based biobank
336 participants (47, 49, 50). We have therefore invited ORCADES and VIKING I participants to consent to
337 return of results. In addition, our recent online cohort study VIKING II/III offered members the option of
338 consent to return of selected clinically actionable results at the point of joining, with an acceptance rate of
339 98% (18). Future research will explore additional genetically drifted loci in Orkney, Shetland and the
340 Western Isles of Scotland in the Viking Genes research cohorts, implement the return of results to
341 consented participants about actionable variants such as the drifted BRCA variants described here, and
342 evaluate the implementation of saliva-based BRCA testing of DNA in those of Westray and Whalsay
343 origins.

344

345 **Data Availability Statement**

346 There is neither Research Ethics Committee approval, nor consent from participants, to permit open
347 release of the individual level research data underlying this study. The datasets generated and analysed
348 during the current study are therefore not publicly available. Instead, the research data and/or DNA
349 samples are available from accessQTL@ed.ac.uk on reasonable request, via managed access, following
350 approval by the Data Access Committee and in line with the consent given by participants.

351 **Acknowledgements**

352 The study team wish to thank staff from the NHS Grampian genetics team and the Viking Genes Study for
353 their contribution to these datasets. DNA extractions were performed at the Edinburgh Clinical Research
354 Facility, University of Edinburgh. Sanger sequencing was performed by Camilla Drake and the technical
355 services team at the MRC HGU. Emily Weiss and Reka Nagy assembled the ORCADES pedigree, and
356 Barbara Gray the Shetland pedigree, using records at the General Register Office and study information,
357 building on earlier pedigree work by Ruth McQuillan and Jim Wilson. We thank Thibaud Boutin for phasing
358 the GSA chip data and Kiera Johnston for help with analysis of other cancer susceptibility genes. The data
359 in the EHR was provided by patients and collected by the NHS as part of their care and support. We would

360 also like to acknowledge the invaluable contributions of the research nurses in Orkney and Shetland and
361 the administrative team in Edinburgh, and the NHS Grampian genetic counselling team for counselling of
362 the carriers identified in the cohorts. Finally, and most importantly, we thank the people of the Northern
363 Isles for their involvement in and ongoing support for our research.

364 **Author Contribution Statement**

365 SK managed the project and drafted the manuscript. LK analysed the exome datasets. MM and LK did the
366 haplotype comparisons. EC and LS provided de-identified clinical data. GT and ARS conceived and
367 managed the Viking Genes exome sequencing. ZM recognised carrier patients through the NHS Grampian
368 clinical genetics service, led clinical aspects of return of results planning and proposed policy. JFW is the
369 Chief Investigator of Viking Genes, was awarded funding to implement the work, did genealogical
370 analyses, interpreted the data and helped draft the manuscript. All authors provided input and feedback
371 on drafts of the manuscript.

372 **Funding**

373 This work was funded by the MRC University Unit award to the MRC Human Genetics Unit, University of
374 Edinburgh, MC_UU_00007/10 and a Wellcome Trust Institutional Translational Partnership Award
375 (University of Edinburgh 222060/Z/20/Z -PII031). LK was supported by an RCUK Innovation Fellowship
376 from the National Productivity Investment Fund (MR/R026408/1).

377 **Ethical Approval**

378 Eligible participants were recruited to ORCADES and the Viking Health Study Shetland (VIKING I), now part
379 of Viking Genes, Research Ethics Committee reference 19/SS/0104. Research participants gave written
380 informed consent for research procedures that included electronic health record linkage and DNA
381 sequencing. The data linkage and access to NHS Scotland-originated data for ORCADES and VIKING I was
382 approved by the Public Benefit and Privacy Panel for Health and Social Care (Ref 1718-0380). This research
383 has also been conducted using data from UK Biobank, as part of project number 19655. Frequencies for
384 the *ATM* and *CHEK2* variants reported here, and the *BRCA2* variant c.517-2A>G numbers in Table 1, were
385 derived from the UK Biobank Whole Genome Sequencing (WGS) project and were obtained from the UK

386 Biobank Allele Frequency Browser (afb.ukbiobank.ac.uk), which was generated by the WGS consortium
387 under the UK Biobank Resource (project ID 52293).

388

389 **Competing Interests**

390 AS and GT are employees and/or stockholders of Regeneron Genetics Center or Regeneron
391 Pharmaceuticals.

519 **Figure and Table Legends**

520 **Figure 1. Grandparental ancestry of *BRCA2* c.517-2A>G carriers in VIKING I.** The first seven bars are
521 parishes or isles of Shetland. The remainder are locations elsewhere in the UK. Of all 36 grandparents of
522 the carriers, 14 (39%) were from Whalsay, with most of the remainder coming from other parishes or isles
523 of Shetland.

524
525 **Figure 2. Outline pedigree of a large kindred from the VIKING I study.** The founder of the kindred was
526 born in Whalsay in 1786, and all descendants enclosed by the blue line were also born there. He had
527 children by two wives. Red outlines are sequenced *BRCA2* c.517-2A>G carriers in VIKING I, dotted red
528 outlines are obligate carriers (parents of carriers, who link to other carriers). Sequenced VIKING I
529 participants without the variant are shown in green. There are many other family members not shown.

530
531 **Figure 3. Visualisation of haplotype sharing across nine Shetland carriers.** The phased Illumina GSA chip
532 genotypes across an 8 Mb region on chromosome 13 are represented for one haplotype from each
533 individual. The pathogenic variant is at 32.33 Mb and a multi-Mb identical-by-descent block is apparent in
534 the centre of the plot. For close relatives, the extent of sharing goes beyond the window shown. Mb,
535 megabase.

536
537 **Table 1. Frequencies of *BRCA2* c.517-2A>G carriers in genomic datasets.** The numbers of carriers are
538 reported for diverse genomic datasets. gnomAD, genome aggregation database; CanVar-UK, Cancer
539 Predisposition Gene Variant Database.

540
541 **Table 2. Carrier frequency estimates of *BRCA* founder variants in the Northern Isles of Scotland and
542 comparison populations.** UKB-EU, UK Biobank European-heritage, exome data reported by CanVar-UK
543 v2.2 release date July 2023 (27). Westray estimates use data from ORCADES on n=1461 self-reported
544 Westray-born grandparents, or 365.25 full Westray genome equivalents. Whalsay estimates use VIKING I
545 individuals with all four grandparents born in Whalsay. N, number of carriers. "One in" gives the reciprocal

546 of the carrier frequency, e.g. one in 105 individuals. Allele frequencies are half the carrier frequencies, for
547 variants such as these, where no homozygotes are observed. Uplift presents the fold uplift in frequency
548 over and above that in UK Biobank European-heritage. The total number of individuals for the sum of the
549 three Ashkenazi founder variants is taken as the average of the counts for the three individual variants.
550 *BRCA2* 517-2A>G is rs81002858; *BRCA1* c.5207T>C is rs45553935; *BRCA2* c.771_775 del is rs80359671;
551 *BRCA1* c.68_69del is rs80357914; *BRCA1* c.5266dup is rs80357906; *BRCA2* c.5946del is rs80359550.

552

553 **Supplementary Table 1 Actionable BRCA1/2 variants in Orkney and Shetland.** Pathogenic or likely
554 pathogenic variants in *BRCA1* or *BRCA2* among 4198 exomes from the Northern Isles. All six variants have
555 3* status in ClinVar as pathogenic and were reviewed by an expert panel, all are autosomal dominant. c.
556 gives the coding DNA position and change; p, the protein position and change; rsid, reference SNP cluster
557 ID; GRCh38, Genome Reference Consortium human build 38; LOF, loss of function.

558

Dataset	Description	Number of Individuals	Carriers of <i>BRCA2</i> c.517-2A>G variant	Non-European Carriers
gnomAD v4.0	Unrelated European (non-Finnish) individuals from genetic studies	549,120 exome sequences	14	0
Viking Health Study Shetland (VIKING I)	Isolate population cohort from Shetland, UK	2,108 exome sequences	9	0
Orkney Complex Disease Study (ORCADES)	Isolate population cohort from Orkney, UK	2,090 exome sequences	0	0
UK Biobank	Cosmopolitan population cohort from UK	458,838 whole genome sequences	15	0
CanVar-UK	Sequenced cancer genes of NHS cancer patients England & Wales	80,722 total probands tested	35	5
Japanese women with breast cancer	Direct sequencing of <i>BRCA1</i> and <i>BRCA2</i> genes	325 women with breast cancer	1	1

Table 1. Frequencies of *BRCA2* c.517-2A>G carriers in genomic datasets.
