Abstract

Background

Children living with HIV have few second-line antiretroviral therapy(ART) options, especially fixed-dose-combinations(FDC).

Methods

Children from Uganda, Zambia, Zimbabwe were randomised to second-line tenofovir alafenamide(TAF)/emtricitabine(FTC) or standard-of-care(SOC) backbone (abacavir(ABC) or zidovudine(ZDV) with lamivudine(3TC)) in the factorial CHAPAS-4 trial. The second randomisation (reported elsewhere) was to dolutegravir(DTG), ritonavir-boosted darunavir(DRV/r), atazanavir(ATV/r) or lopinavir(LPV/r) as anchor drug. All drugs were dosed using WHO weight-bands and children <25kg received a new paediatric TAF/FTC(15/120mg) FDC tablet. The primary endpoint was viral load(VL)<400copies/ml at week-96, analysed using logistic regression, hypothesising that TAF/FTC would be non-inferior to SOC (10% margin). Secondary endpoints included safety and immunological outcomes. Analyses were intention-to-treat.

Results

919 children 3–15years, 497(54%) male, median[IQR] baseline viral load(VL) 17,573copies/ml [5549-55,700] and CD4 count 669cells/mm³[413-971], spent 99% of time on allocated NRTI backbone. At week-96, 406/454(89.4%) receiving TAF/FTC vs. 378/454(83.3%) receiving SOC had VL<400copies/mL (adjusted difference[95%CI]: 6.3%[2.0%,10.6%], p=0.004), with no evidence that this varied by ABC/3TC or ZDV/3TC SOC. CD4 count improved similarly in both arms. Growth was better with TAF/FTC vs. SOC, without evidence of excess weight-gain with any backbone/anchor drug combination (including DTG±TAF/FTC, interaction p=0.51). Bone health parameters were similar between arms, irrespective of anchor drug. One child died (treatment-unrelated); 29(3%) had serious adverse events without differences between arms.

Conclusions

TAF/FTC was virologically superior to SOC ZDV/3TC or ABC/3TC with a favourable safety profile, irrespective of anchor drug. Development of child-friendly TAF/FTC FDCs (±anchor drug) would increase cost-effective ART options for children and reduce drug access gaps between children and adults. (ISRCTN22964075)

Background

At the end of 2022, of the estimated 1.5 million children living with HIV (CLHIV) under 15 years globally, 57% were receiving antiretroviral therapy (ART), the majority living in Africa.¹⁻³

Estimates from global cohort studies suggest that around 5-10% children have switched to second-line ART,^{4,5} but few to third-line. The need for access to safe, effective ART options for children with first-line ART regimen failure will increase in coming years, even as dolutegravir (DTG) is rolled-out for children for both first-and second-line ART.

The World Health Organization (WHO) currently recommends two nucleoside/nucleotide reverse transcriptase inhibitor drugs (NRTIs) as a backbone in both first-line and second-line ART regimens. These are sequenced between abacavir/lamivudine (ABC/3TC) and zidovudine/lamivudine (ZDV/3TC), from first-line to second-line ART. Tenofovir disoproxil fumarate (TDF) with 3TC or emtricitabine (FTC) is recommended for first and/or second-line ART for adolescents >30kg. Data from adult trials suggests tenofovir is superior to ZDV.^{6,7} However, concerns about bone health, renal toxicity and poor availability of paediatric formulations limits use of TDF in younger children.⁸

Tenofovir alafenamide (TAF)/emtricitabine (FTC) (15/120mg) is a new small, paediatric fixed-dose-combination (FDC) including TAF, a prodrug of tenofovir, with lower milligram dosage and more favourable bone and renal safety profiles than the TDF prodrug. Unlike TDF, where tenofovir is widely distributed following absorption, tenofovir from TAF remains mostly restricted to cells with high carboxyesterase and cathepsin A activity such as hepatocytes and lymphocytes, resulting in lower

tenofovir plasma levels but higher intracellular concentrations and lower toxicity compared to TDF.^{9,10} There are limited data on TAF in children in Africa. We recently reported the first pharmacokinetic (PK) data for African children aged 3-15 years in CHAPAS-4 receiving TAF/FTC with either DTG or a boosted protease inhibitor (bPI), showing that tenofovir concentrations were similar to those that are safe and effective in adults.¹¹

There are no paediatric data comparing TAF/FTC to WHO-recommended NRTI backbone options (ABC/3TC and ZDV/3TC). In CHAPAS-4, we compared the efficacy and safety of TAF/FTC vs. ABC/3TC or ZDV/3TC in African children starting second-line ART.

Methods

CHAPAS-4 (ISRCTN22964075) was a randomised, open-label trial with a factorial design (2X4). Children were randomised to one of two NRTI backbones (TAF/FTC or SOC (ABC/3TC or ZDV/3TC, whichever had not been used first-line)). They were simultaneously randomized to one of four anchor drugs (DTG, darunavir/ritonavir (DRV/r), atazanavir/ritonavir (ATV/r) or lopinavir/ritonavir (LPV/r), reported elsewhere). The doses of trial drugs followed WHO weight bands (Table S1). Of note, the TAF doses were the same irrespective of anchor drug.

The trial was approved by ethics committees in Uganda, Zambia, Zimbabwe, South Africa and United Kingdom. The protocol is available at www.mrcctu.ucl.ac.uk/studies/all-studies/c/chapas-4.

Participants were recruited at six hospitals in three sub-Saharan African countries: Uganda (Joint Clinical Research Centre, Kampala; Joint Clinical Research Centre, Mbarara), Zambia (University Teaching Hospital, Lusaka; Arthur Davison Children's Hospital, Ndola) and Zimbabwe (University of Zimbabwe Clinical Research Centre, Harare; Mpilo Central Hospital, Bulawayo).

Participants were CLHIV aged 3-15 years, weighing ≥ 14 kg, requiring switch from first-line NNRTI-based ART for virologic failure defined as viral load(VL) >1000 copies/ml with/without immunological and/or clinical failure. Children had to be able to swallow tablets, and post-menarchal females

required a negative pregnancy test. Guardians provided written informed consent, with additional assent from older children, according to national guidelines. Children were excluded if they had severe hepatic impairment (alanine aminotransferase (ALT) ≥ 5 times upper-limit of normal (ULN), or ALT $\geq 3 \times$ ULN and bilirubin $\geq 2 \times$ ULN or clinical liver disease).

Randomisation was stratified by centre and first-line NRTI (ABC/3TC or ZDV/3TC). A computer-generated sequential randomisation list with variably sized permuted blocks was prepared by the trial statistician and incorporated securely into an online trial database. The allocation was concealed until eligibility was confirmed by local centre staff, who then performed the randomisation.

Participants were seen at screening, ART switch (week 0), 2, 6, 12 weeks and 12 weekly thereafter to at least 96 weeks (primary endpoint); extended follow-up continued through 2 February 2023. Visits included clinical and laboratory efficacy and safety assessments. Children with prevalent tuberculosis at enrolment or subsequent incident tuberculosis had TAF and anchor drugs changed during anti-tuberculosis treatment to adjust for rifampicin interaction. Measures were taken to ensure participant follow up during the COVID-19 pandemic (Panel 1 in Supplementary Appendix 1).

Primary outcome was VL < 400 copies/ml at week 96 (death counted as ≥ 400). Secondary efficacy outcomes were VL < 60 and < 1000 copies/ml at week 96, death/WHO 3/4 events, changes in CD4 (absolute and percentage), and genotypic resistance (assays ongoing). Secondary safety outcomes were grade 3/4, serious, and ART-modifying adverse events (AEs); and changes in cholesterol (total, low-density lipoprotein (LDL), high-density lipoprotein (HDL), triglycerides, bilirubin and creatinine clearance (CrCl). Other outcomes included changes in weight-, height- and body mass index (BMI)-for-age and bone mineral density Z-scores.

In addition, cost-effectiveness analyses were conducted to compare TAF/FTC versus SOC arms over the full 96 weeks of the trial. Health was measured in quality-adjusted life-years (QALYs) and costs, clinic visits and hospital stays, both discounted at 3% per annum. Further detail is included on cost effectiveness in Supplementary Appendix 2.

Assuming 80.0%-87.5% of children on SOC achieved VL <400 copies/ml at week 96, 920 children provided $\geq 95\%$ power to demonstrate that TAF was non-inferior (10% margin) to SOC (two-sided $\alpha=5\%$), assuming 2.5% loss-to-follow-up (reduced from 10% in original protocol). An independent data monitoring committee reviewed the interim data at four meetings using the Haybittle–Peto criterion (99.9% confidence interval). Analyses were intention-to-treat. Analyses of the primary endpoint used logistic regression (adjusting for stratification factors), then marginal estimation of risk differences. Secondary per-protocol analysis included children who received the randomised NRTI backbone for >90% of follow-up. Sub-group analysis used interaction tests. For VL <60 and <1000 copies/ml, analysis was similar. For death/WHO 3/4 events, and grade 3/4, serious and ART-modifying AEs, groups were compared via Cox regression (unadjusted). Changes in continuous outcomes were analysed using Normal generalised estimating equations adjusting for visit, stratification factors and baseline (and interactions between these factors and visit), for an overall test of difference between groups over all visits (independent correlation). Analyses were conducted using Stata (version 17.0). The 95% confidence intervals were not adjusted for multiple testing.

The funder, European Developing Country Clinical Trial Partnership (EDCTP), and pharmaceutical companies donating additional funding (Gilead Sciences, Johnson and Johnson) and trial medications (ViiV Healthcare, Gilead sciences, Johnson and Johnson, CIPLA) did not participate in design, conduct or analysis of the trial.

Results

919 children were randomised between 17 December 2018 and 1 April 2021, 458 to TAF/FTC and 461 to SOC (Figure 1). Baseline characteristics were similar between arms (Table 1 and Table S2). 497/919 (54.1%) children were male with median age 10 (inter-quartile range (IQR) 8,13) years. 777/919 (84.5%) were WHO stage 1/2. Median weight-for-age Z-score was -1.6 (IQR -2.4,-0.9); height-for-age Z-score -1.6 (-2.3,-0.8); body mass index (BMI)-for-age Z-score -1.0 (-1.7,-0.4). Median VL was 17573

copies/mL (IQR 5549,55700); CD4 count 669 cells/mm³ (413,971) and CD4% 28% (19%,36%). Median time on first-line ART was 5.6 years; prior to randomisation 44% were on nevirapine and 56% on efavirenz.

In SOC, 217/461 (47.1%) initiated ABC/3TC and 244 (52.9%) ZDV/3TC. Over 96 weeks, 98.9% of visits were attended and only 11 children (1.2%) were lost to follow-up (Figure 1). 674 (73%) entered extended follow-up (median 60 (IQR 30,75) additional weeks). Prior to week 96, children spent 99.1% of time on allocated NRTI backbone (99.5% TAF/FTC vs. 98.8% SOC) and only five (0.5%) initiated third-line ART (2 (0.4%) TAF/FTC vs. 3 (0.7%) SOC). In extended follow-up, children spent 93.5% of time on allocated NRTI (95.6% TAF/FTC, 91.4% SOC) (Figure S1 in Supplementary Appendix 1).

Viral suppression was high in both arms (Figure 2). At week 96, 406/454 (89.4%) TAF/FTC vs. 378/454 (83.3%) SOC had VL <400copies/mL (adjusted difference +6.3% [95% confidence interval (CI) +2.0%,+10.6%]; p=0.004). Therefore, TAF/FTC was non-inferior to SOC according to the pre-specified (-)10% margin, and in fact superior. There was no evidence of heterogeneity of the effect of TAF/FTC vs. SOC in any of 11 sub-groups ($p_{\text{interaction}} > 0.1$) (Figure S2 in Supplementary Appendix 1), including first-line NRTI (ABC vs. ZDV) ($p_{\text{interaction}} = 0.97$), randomised anchor drug, country and baseline VL. Results of per-protocol analyses were similar: 403/449 (89.8%) TAF/FTC vs. 370/445 (83.1%) SOC had VL <400copies/mL (adjusted difference 6.8% [2.4%,11.1%]; p=0.002). Suppression <60 and <1000c/ml VL thresholds were similar, as were results at weeks 48 and 144 (Table S3).

Over 96 weeks, there were only nine WHO stage 3/4 events and one child died (TAF/FTC, from hypotension/toxic shock secondary to severe malnutrition, judged unrelated to ART) (WHO 3/4 event/death: 5 TAF/FTC vs. 5 SOC). CD4 count improved in both arms (+103 vs. +67 cells/mm³ at week 96; mean difference between arms (averaged over all visits to week 96) +24 [95% CI -9,+58]), as did CD4% (+7.3% vs. +7.5%) (+0.4% [-0.4%,+1.1%]). In extended follow-up, there was no evidence of difference between arms in either CD4 or CD4% (Figure S3 in Supplementary Appendix 1).

Over 96 weeks, weight-, height- and BMI-for-age increased significantly more with TAF/FTC vs. SOC (mean difference in Z-scores between arms was +0.09 [95% CI +0.04,+0.13], 0.04 [+0.01,+0.07] and 0.10 [+0.04,+0.16], respectively); in extended follow-up, increases were generally maintained and similar (Figure S4 in Supplementary Appendix 1). Comparing TAF/FTC vs. SOC at week 96, the corresponding weight increase was 7.0 vs. 6.2kg; height increase was 10.2 vs. 9.8cm.

Over 96 weeks, 127/919 (13.8%) children experienced a total of 176 grade 3/4 adverse events (AEs) (63 (13.8%) TAF/FTC vs. 64 (13.9%) SOC) ($p=0.93$ Cox model) (Table 2; Table S4), including eight “specific infections”, all in SOC (4 malaria, 3 tuberculosis, 1 herpes zoster). 29 (3.2%) children experienced a total of 31 serious adverse events (SAEs) (15 (3.3%) TAF/FTC vs. 14 (3.0%) SOC) ($p=0.84$) (Table S5), most were hospitalisations, with intercurrent infections. 24 (2.6%) children experienced a total of 41 ART-modifying AEs (any grade) (11 (2.4%) TAF/FTC vs. 13 (2.8%) SOC) ($p=0.68$), of which 33 were protocol-specified modifications due to tuberculosis (Table 2).

There was no evidence of differences in fasting lipids (total, HDL, LDL cholesterol and triglycerides) between arms over 96 weeks ($p>0.1$), nor in extended follow-up ($p>0.05$) (Figure S5 in Supplementary Appendix 1).

Calcaneal ultrasounds performed on all children showed no evidence of differences between arms over 96 weeks ($p>0.3$), nor in extended follow-up ($p>0.2$). DEXA scans performed in 170 children at weeks 0, 48 and 96 showed no evidence of differences between arms in lumbar total bone mineral content (BMC), bone mineral density (BMD) or BMD Z-score (unadjusted for height) and total body less head (TBLH) BMD Z-score (all $p>0.05$) TBLH BMC and BMD increased slightly more with TAF/FTC vs. SOC ($p=0.02$ and $p=0.04$, respectively; Figure 3).

There was a small reduction in mean CrCl in both arms at week 96, which was greater in TAF vs. SOC (mean -16 vs. -11ml/min; $p=0.0007$), and which persisted in extended follow-up ($p=0.001$) (Figure S6 in Supplementary Appendix 1). However, no child discontinued treatment in the TAF arm for renal

dysfunction. There was no evidence of differences in phosphate excretion between arms (Figure S7 in Supplementary Appendix 1).

Cost-effectiveness Analysis

There was no significant difference in QALYs so the primary analysis focused on costs only. TAF/FTC was less costly than SOC by \$37.68, with a 100% probability of being cost-saving. This saving could be used to generate 0.0754 QALY elsewhere based on a cost-effectiveness threshold of \$500 per QALY. Further detail is included in Cost Effectiveness Supplementary File.

Discussion

Although under 10% of the 1.5 million CLHIV currently on ART globally are on second-line ART,^{4,5} this proportion is likely to increase with greater access to first-line ART and VL testing. CHAPAS-4 is the first large randomized trial to evaluate NRTI backbone options including TAF for second-line ART in African children. It found that TAF/FTC provides superior viral suppression compared to current SOC of ABC/3TC or ZDV/3TC. It is also the first time a small paediatric FDC of FTC/TAF (120/15mg) has been used in children. Children did very well clinically with only one death over 96 weeks in a child with advanced disease, and very few required hospitalisation or experienced HIV disease progression. This is in part attributable to the relatively high CD4 counts at baseline and supports the principle of not delaying switch to second-line until evidence of significant immunocompromise.

The superior viral suppression of 89.4% at 96 weeks observed with TAF/FTC is comparable to the 93-100% reported in four small single-arm paediatric trials of TAF conducted in Africa, Asia and North America.¹² Of note, over 85% were virologically suppressed at baseline in these studies, whereas all children in CHAPAS-4 had VL >400c/ml at baseline. Our results are also similar to the 86-92% viral suppression rates observed on TDF and TAF in the adult African NADIA and VISEND trials respectively,^{6,7} and the 84-86% VL suppression at 96 weeks observed in a pooled analysis of TDF/TAF in 14 adult trials.¹³

Weight-, height- and BMI-for-age z-scores increased more with TAF/FTC, suggesting overall better growth. We did not observe excessive weight gain over 96 weeks on TAF/FTC, including among children also taking DTG. The higher weight-gain observed with TAF/FTC was small in absolute terms and paralleled by an increase in height, and could be a consequence of improved virological suppression. Of note, children generally had normal or low weight and BMI-for-age at baseline, with only 5 children having a BMI for age z-score of ≥ 2 . Among adults from the Zambian VISEND trial, greater weight gain (by ~ 2 kg) was observed among participants (especially women) on TAF with DTG compared with ZDV with bPI or TDF with DTG.⁶

TAF was safe with no evidence of bone toxicity, and if anything, greater increases in BMD as assessed by TBLH DEXA scans vs. SOC; this was irrespective of anchor drug (DTG or bPIs). These findings, alongside the additional benefits of small pill size, once-daily administration, low cost and low risk of hypersensitivity, make TAF a valuable second-line option. Although we observed that mean CrCl decreased slightly more over 96 weeks with TAF/FTC, values remained within normal limits, with no associated grade 3/4 adverse events, and are unlikely to be clinically significant; no child discontinued medication for renal dysfunction, and phosphate excretion was not increased.

The within trial economic analysis showed that TAF/FTC would be cost-effective compared to SOC with large cost-savings which could generate health benefits elsewhere. Development and provision of generic TAF FDC's would potentially further enhance these benefits.

The CHAPAS-4 trial was conducted at six centres in three African countries, including three centres outside capital cities, increasing generalizability of results across sub-Saharan Africa. However, one limitation is that the trial enrolled children with NNRTI-based first-line ART failure, a situation which is becoming less common with first-line DTG rollout. Caution may be needed when extrapolating to using TAF for first-line treatment or in children with DTG-based first-line ART failure, although it is likely that TAF would also have excellent safety and efficacy in these circumstances.⁸

In conclusion, TAF/FTC is a highly efficacious, safe and cost-effective addition to the NRTI backbone options for second-line ART for children living with HIV. Results support development of child friendly FDCs of TAF/FTC with or without anchor drugs (e.g. DTG or bPI). The results support the inclusion of TAF containing regimens on the priority list of the WHO Paediatric Drug Optimization (PADO) program,¹⁴ so paediatric formulations are prioritised for development, allowing them to be considered for inclusion in future WHO HIV paediatric treatment guidelines.

The trial was approved by ethics committees in Uganda (Joint Research Ethics Committee (JREC)), Zambia (University of Zambia Biomedical Research Ethics Committee (UNZABREC)), Zimbabwe (Joint Research Ethics Committee University of Zimbabwe College of Health Sciences (JREC), Research Council Zimbabwe (RCZ)), South Africa (University of Cape Town Human Research Ethics Committee) and United Kingdom (UCL Research Ethics Committee).

Role of the funding source

The CHAPAS-4 Trial is sponsored by University College London (UCL), with central management by the Medical Research Council (MRC) Clinical Trials Unit at UCL supported by MRC core funding (MC_UU_00004/03). The main funding for this study is provided by the European and Developing Countries Clinical Trials Partnership. This project is part of the EDCTP programme supported by the European Union (EDCTP; TRIA2015-1078). This publication was produced by CHAPAS-4 which is part of the EDCTP programme supported by the European Union. The views and opinions of authors expressed herein do not necessarily state or reflect those of EDCTP. Additional funding for the

CHAPAS-4 extended follow up was provided by UNIVERSAL project. This project, grant number RIA2019PD- 2882, is part of the EDCTP2 programme supported by the European Union.

Additional funding and drug donations were received from Janssen Pharmaceuticals, and Gilead Sciences Inc. Drug donations were also received by Viiv Healthcare and Cipla. Drugs were also purchased from Emcure Pharmaceuticals.

Table 1: Baseline characteristics

	Standard-of-care N=461	TAF N=458	Total N=919
Male	256 (55.5%)	241 (52.6%)	497 (54.1%)
Age (years)	10 (7, 13)	10 (8, 13)	10 (8, 13)
3-4	21 (4.6%)	18 (3.9%)	39 (4.2%)
5-9	178 (38.6%)	180 (39.3%)	358 (39.0%)
10-15	262 (56.8%)	260 (56.8%)	522 (56.8%)
WHO stage			
1	244 (52.9%)	239 (52.2%)	483 (52.6%)
2	140 (30.4%)	154 (33.6%)	294 (32.0%)
3	63 (13.7%)	50 (10.9%)	113 (12.3%)
4	14 (3.0%)	15 (3.3%)	29 (3.2%)
CD4 (cells/mm ³)*	667 (405, 963)	673 (434, 982)	669 (413, 971)
CD4%**	27.5 (19.0, 35.4)	28.3 (20.3, 37.0)	28.0 (19.2, 36.0)
VL (copies/ml)	17909 (5417, 58359)	17265 (5764, 50655)	17573 (5549, 55700)
Weight (kg)	26.1 (20.2, 33.5)	25.8 (21.0, 32.8)	25.9 (20.5, 33.1)
Weight-for-age Z-score***	-1.6 (-2.4, -0.9)	-1.6 (-2.4, -0.9)	-1.6 (-2.4, -0.9)
Height (cm)	130.9 (118.0, 142.5)	130.1 (120.7, 141.6)	130.5 (119.4, 142.0)

Height-for-age Z-score***	-1.5 (-2.3, -0.9)	-1.6 (-2.4, -0.8)	-1.6 (-2.3, -0.8)
BMI (kg/m ²)	15.4 (14.4, 16.5)	15.5 (14.3, 16.8)	15.5 (14.3, 16.7)
BMI-for-age Z-score***	-1.0 (-1.6, -0.4)	-0.9 (-1.8, -0.3)	-1.0 (-1.7, -0.4)
Time on first-line ART (years)	5.6 (3.2, 7.8)	5.5 (3.3, 7.7)	5.6 (3.3, 7.8)
First-line NRTI			
Abacavir	244 (52.9%)	246 (53.7%)	490 (53.3%)
Zidovudine	217 (47.1%)	212 (46.3%)	429 (46.7%)
First-line NNRTI			
Efavirenz	247 (53.6%)	267 (58.3%)	514 (55.9%)
Nevirapine	214 (46.4%)	191 (41.7%)	405 (44.1%)
Randomised anchor drug			
LPV/r	115 (24.9%)	112 (24.5%)	227 (24.7%)
ATV/r	115 (24.9%)	116 (25.3%)	231 (25.1%)
DRV/r	114 (24.7%)	118 (25.8%)	232 (25.2%)
DTG	117 (25.4%)	112 (24.5%)	229 (24.9%)

ART denotes antiretroviral therapy, ATV/r ritonavir-boosted atazanavir, BMI body mass index, DRV/r ritonavir-boosted darunavir, DTG dolutegravir, LPV/r ritonavir-boosted

lopinavir, NNRTI non-nucleoside reverse transcriptase inhibitor, NRTI nucleoside/nucleotide reverse transcriptase inhibitor, VL HIV viral load, and TAF tenofovir

alafenamide fumarate

Values are n (%) or median (IQR). There was no evidence of imbalances in baseline characteristics between the randomised groups ($p > 0.1$)

*Missing for 13 patients

**Missing for 14 patients

***Z-scores determined using British 1990 Reference data, which covers the full age range of CHAPAS-4 children

Table 2: Grade 3 and 4, serious and ART-modifying adverse events during 96-week follow-up

	Standard-of-care N=461	TAF N=458	Total N=919
Grade 3/4	64 (13.9%) 93	63 (13.8%) 83	127 (13.8%) 176
Raised bilirubin	25 (5.4%) 32	34 (7.4%) 36	59 (6.4%) 68
Serious adverse event	14 (3.0%) 14	15 (3.3%) 17	29 (3.2%) 31
Death	0 (0.0%) 0	1 (0.2%) 1*	1 (0.1%) 1
Life threatening	1 (0.2%) 1	1 (0.2%) 2	2 (0.2%) 3
Caused or prolonged hospitalisation	13 (2.8%) 13	14 (3.1%) 16	27 (2.9%) 29
Other important medical condition	1 (0.2%) 1	1 (0.2%) 1	2 (0.2%) 2
ART-modifying	13 (2.8%) 22	11 (2.4%) 19	24 (2.6%) 41
Psychiatric disorder	0 (0.0%) 0	1 (0.2%) 1	1 (0.1%) 1
Acute hepatitis	1 (0.2%) 1	0 (0.0%) 0	1 (0.1%) 1
Hypersensitivity reaction	2 (0.4%) 4	0 (0.0%) 0	2 (0.2%) 4
Tuberculosis	9 (2.0%) 16	9 (2.0%) 17	18 (2.0%) 33

	Standard-of-care N=461	TAF N=458	Total N=919
Pregnancy	0 (0.0%) 0	1 (0.2%) 1	1 (0.1%) 1
Anaemia	1 (0.2%) 1	0 (0.0%) 0	1 (0.1%) 1

ART denotes antiretroviral therapy and TAF tenofovir alafenamide fumarate

Excluding extended follow-up after 96 weeks

Showing number of patients with one or more event (% of patients) number of events

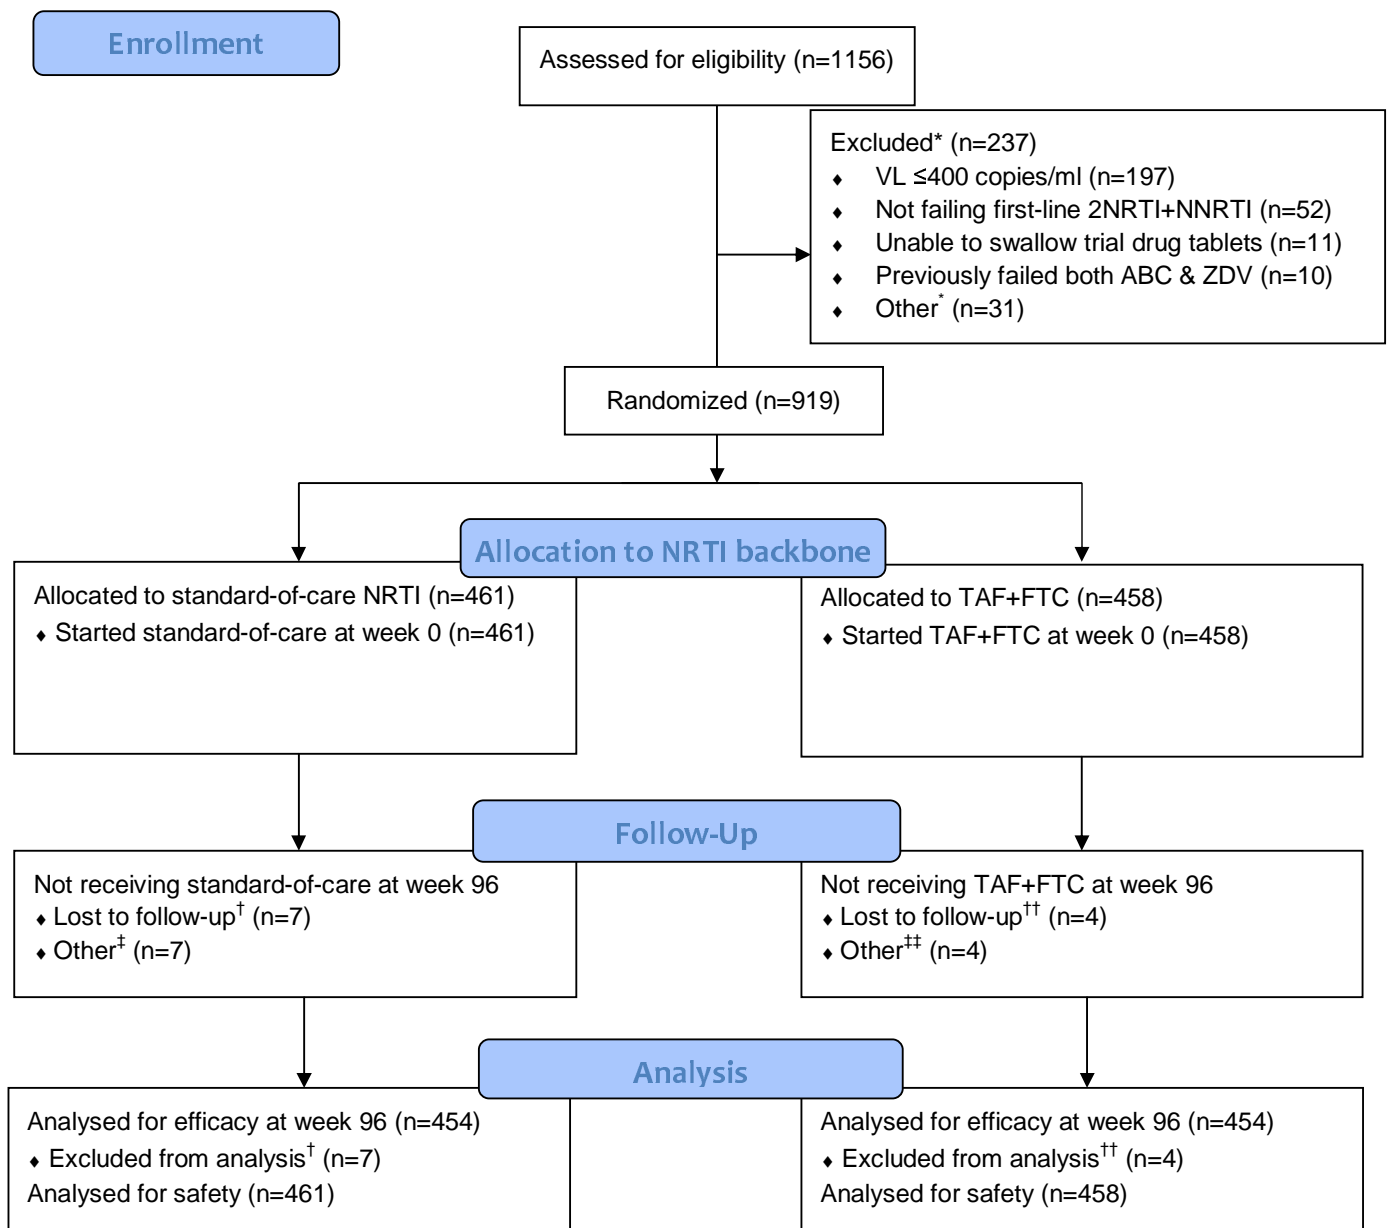

*Hypotension/shock/toxic shock (secondary: severe malnutrition; candidiasis of oesophagus, trachea, bronchi or lungs)

Figure 1 CONSORT flow diagram

Figure 2 Percentage of children with HIV viral load (copies/ml) <400 copies/ml (a), <60 copies/ml (b) and <1000 copies/ml (c), over time during the main trial and during extended follow-up

Figure 3 Change in (a) Lumbar total and (b) total body less head (i) bone mineral content, (ii) bone mineral density and (iii) bone mineral density Z-score

Figure 1 CONSORT flow diagram

ABC denotes abacavir, FTC emtricitabine, NNRTI non-nucleoside reverse transcriptase inhibitor, NRTI nucleoside/nucleotide reverse transcriptase inhibitor, TAF tenofovir alafenamide fumarate, VL HIV viral load, and ZDV zidovudine.

Note: All children also allocated to anchor drug

* Reasons are not mutually exclusive therefore total to more than the total number of non-randomisations

† Other reasons: declined to participate (n=7), did not return for enrolment within window (n=4), not aged 3-15 (n=4), biochemical (n=3), previously failed ritonavir-boosted lopinavir (n=2), contraception (n=1), contraindications (n=1), co-morbidities (n=1), died (n=1), other (n=9)

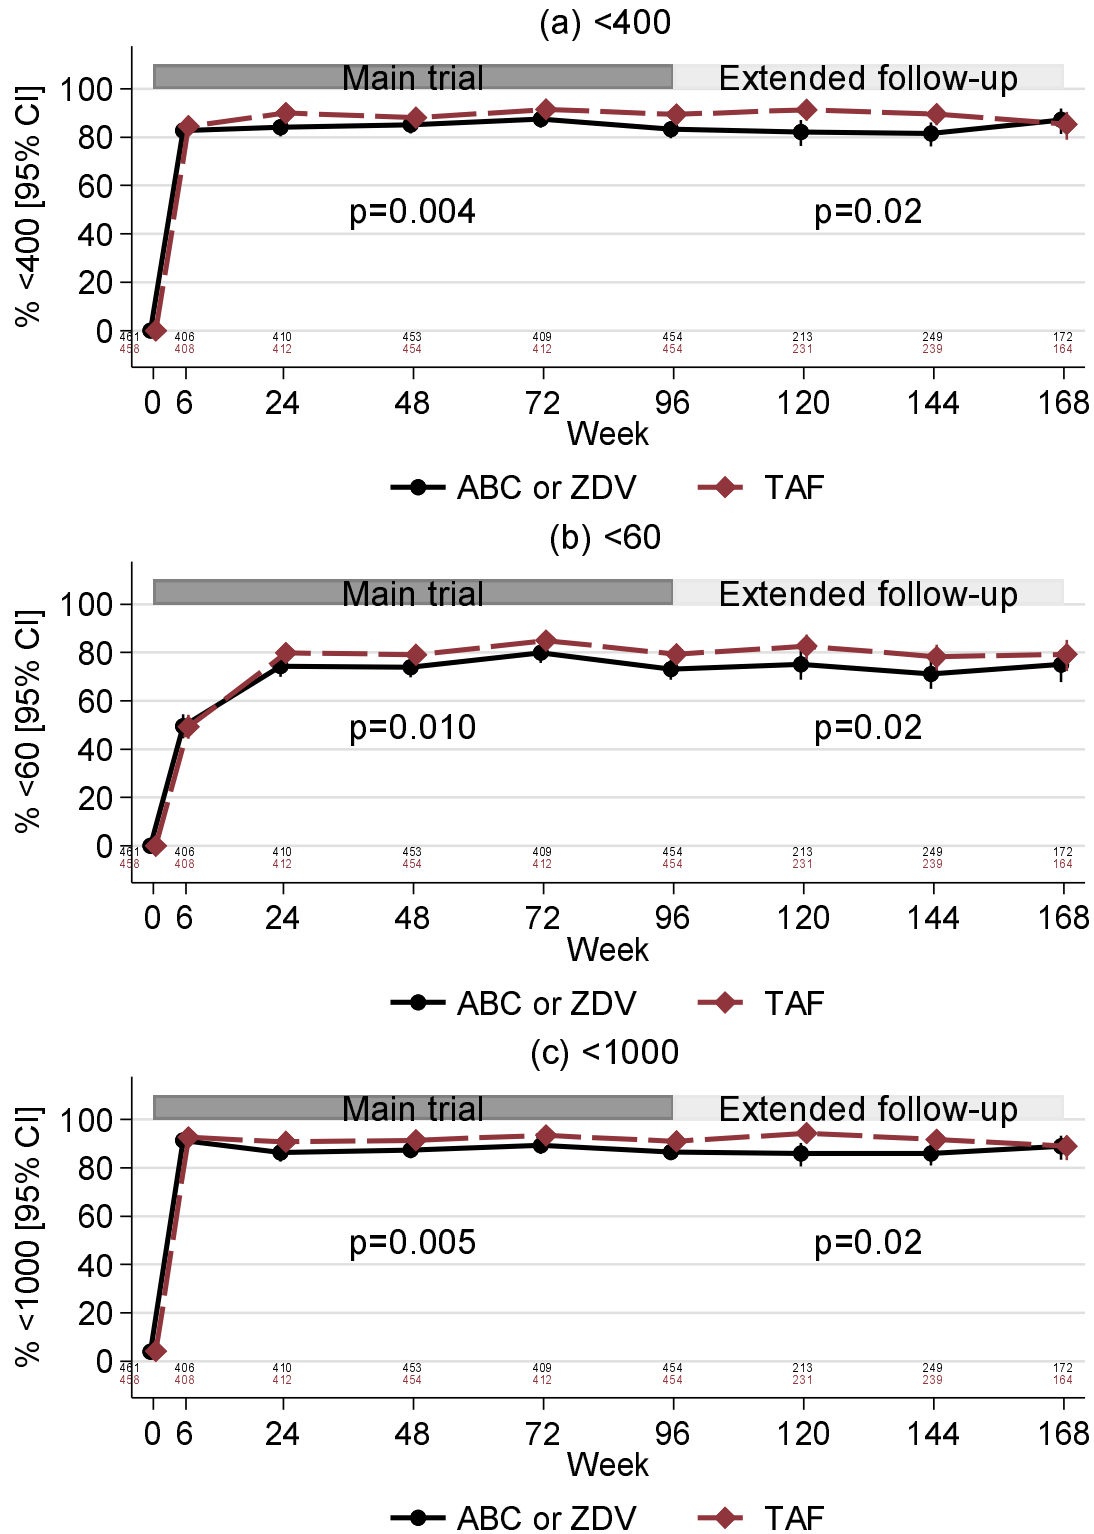

‡ Moved (n=4), social problems (n=3)

†† Moved (n=4)

‡‡ Started third-line (n=3), hypersensitivity (n=2), anaemia (n=1), patient decision (n=1)

‡‡ Patient decision (n=3), interaction (n=1)

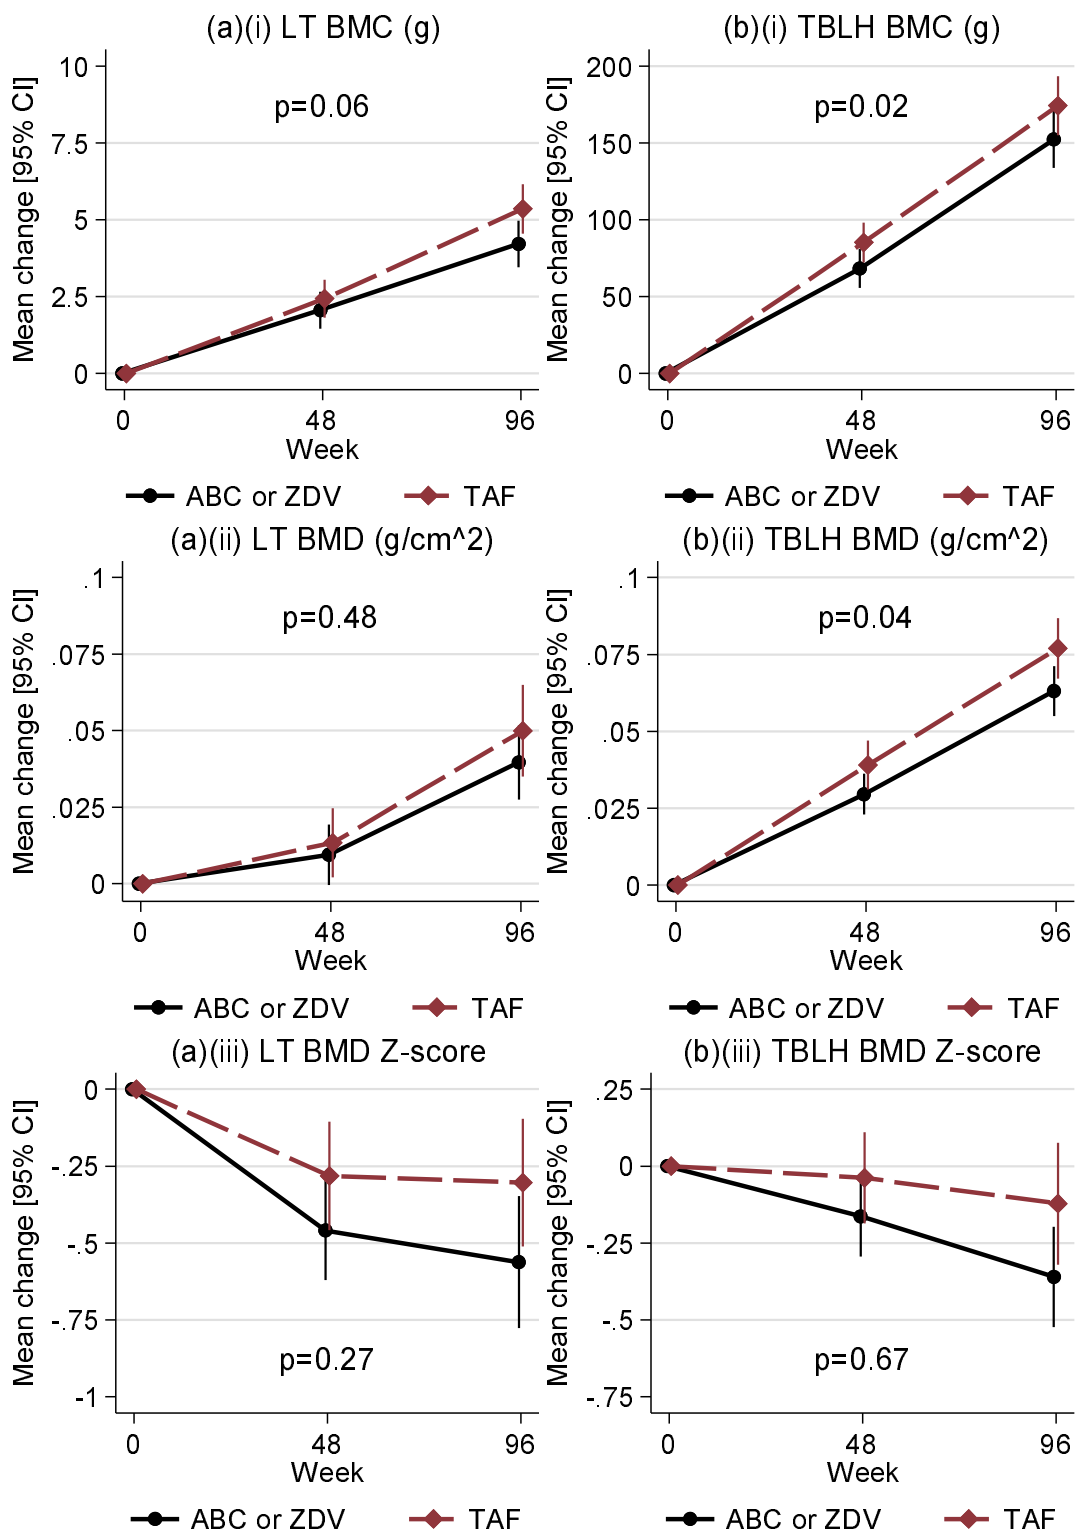

Figure 2: Percentage of children with HIV viral load <400 copies/ml (a), <60 copies/ml (b) and <1000 copies/ml (c), over time during the main trial and during extended follow-up

Extended follow-up p-values include all of extended follow-up

ABC denotes abacavir, TAF tenofovir alafenamide fumarate and ZDV zidovudine

Figure 3: Change in (a) Lumbar total and (b) total body less head (i) bone mineral content, (ii) bone mineral density and (iii) bone mineral density Z-score

DEXA not carried out in extended follow-up

ABC denotes abacavir, BMC bone mineral content, BMD bone mineral density, DEXA dual energy x-ray absorptiometry, LT lumbar total, TAF tenofovir alafenamide fumarate, TBLH total body less head and ZDV zidovudine
