Abstract

Our demographic analyses aimed to evaluate the impact of COVID-19 on life

expectancy and life span equality in Japan from 2020-22. Our prefectural analysis of

2021–22 life expectancy change and annual per-population COVID-19 cases, person-

days in intensive care, and reported COVID-19 deaths showed no significant

correlations, unlike our analysis from 2020–21. However, decomposition analysis

revealed substantial life expectancy shortening attributable to the population over 35

years old. It also showed large increases in deaths caused by cardiovascular or

respiratory disorders as well as COVID-19. Whole-population life span equality

declined in 2020 but increased in 2021 and 2022 despite the shorter life expectancy,

which was likely attributable to increased mortality among older people. This study

revealed how the impact of COVID-19 has become less ascertained in official

epidemiological statistics in 2022, and how the pandemic has substantially altered the

death cause structure and the distribution of age at death.

**Keywords: COVID-19; life expectancy; excess mortality; Arriaga Method; life

span equality; life table entropy; Japan**

33   Introduction

Since the start of the COVID-19 pandemic in Wuhan, China in November 2019,

evidence of the pandemic's impact on mortality has accumulated globally, with

substantial geographical heterogeneity. (Bilal et al. 2021; COVID-19 Excess Mortality

Collaborators 2022; Msemburi et al. 2023; GBD 2021 Demographics Collaborators

2024; Schöley et al. 2022; Aburto et al. 2022) Global studies suggest that from January

1st, 2020 to December 31st, 2021, excess deaths worldwide were in the range of 14.9–

15.9 million, with a large proportion attributed to India and the United

States.(Msemburi et al. 2023; GBD 2021 Demographics Collaborators 2024) Published

studies suggest that the global life expectancy change was −1.6 years from 2019 to

2021, when many countries showed bounce-backs from the shortening in 2020.

However, other countries faced sustained shortening into 2021.(GBD 2021

Demographics Collaborators 2024; Schöley et al. 2022; Aburto et al. 2022)

It is now several years since the emergence of COVID-19, and the evaluation of the

mortality impact of the condition has become more difficult for several reasons. One

reason is changes in the official COVID-19 statistics, which are provided by public

health agencies around the world and reflect epidemic activity. These are now less

rigorous than in 2020, because most countries have gradually diminished their effort

either to control the spread of COVID-19 or to maintain a meticulous surveillance

system. Another reason is the change in the nature of deaths associated with COVID-19

since the introduction of vaccines against the disease in late 2020. The direct mortality

impact of COVID-19 has been alleviated by these vaccines, but a substantial proportion

of deaths are caused indirectly through complications such as cardiovascular disorders,

or by limited access to healthcare services when the healthcare capacity or ambulance

system were overwhelmed by the increased case load pressure of COVID-19. (Schöley

et al. 2022; Watson et al. 2022; Link-Gelles et al. 2023; Rossman et al. 2021; Hayashi

and Nishiura 2022; French et al. 2021; Knight et al. 2022; Raisi-Estabragh et al. 2022;

Lee et al. 2023; Kayano et al. 2022) The ongoing emergence of SARS-CoV-2 variants

with a high capability of immune evasion and transmission may have worsened the

health impact of COVID-19, but understanding the true burden has remained a

challenging task.(Andrews et al. 2022; Carabelli et al. 2023)

Direct approaches to estimating the mortality impact of COVID-19 are therefore

challenging, including in Japan. There, the epidemic size of COVID-19 was greatest

upon the emergence of SARS-CoV-2 Omicron (B.1.1.529) lineage variants. In line with

other regions, Japan has been severely affected by COVID-19 in terms of excess

mortality and life expectancy shortening. (Bilal et al. 2021; Msemburi et al. 2023; GBD

2021 Demographics Collaborators 2024; Schöley et al. 2022; Lee et al. 2023; Munira,

Okada, and Nishiura 2023; Woolf, Masters, and Aron 2021; Nomura et al. 2022;

"Excess and Exiguous Deaths Dashboard in Japan" 2024) The updated estimates by the

National Institute of Population and Social Security Research suggest that life

expectancy at birth has shortened for two consecutive years, from 84.58 years in 2021

to 84.10 in 2022 for the total population. However, it is not clear whether the cause-

specific impact of this shortening has changed since 2021. It is also not clear how the

contribution of cardiovascular, respiratory, and neoplastic disorders in 2021 have

changed. (Munira, Okada, and Nishiura 2023) From a demographic perspective, the

change in life span equality during and since the COVID-19 pandemic is also

interesting. One measure of life span equality, or, evenness of life span, is the logarithm

of the inverse of life table entropy. Global and historical demographic analysis suggests

that the trends in life expectancy at birth and life span equality have been in line with

each other. (Aburto et al. 2020; Colchero et al. 2016) However, this might not be the

case when the age–mortality structure changes drastically. For example, during the

COVID-19 epidemic in Japan, the mortality increase in 2021 contributed substantially

to shorter life expectancy. (Munira, Okada, and Nishiura 2023)

To examine the demographic impact of the COVID-19 epidemic in 2022 in Japan, we

investigated the relationship between reported COVID-19 burden at the prefectural level

and life expectancy. We also decomposed the year-on-year life expectancy change from

2019–22 by age groups and major causes of death, and evaluated the lifetime loss by

age and life span equality during the COVID-19 epidemic.

Methods

epidemiological data

We used the data on deaths and exposure-to-risk populations available in the

Japanese Mortality Database (JMD), which was available for the whole of Japan and by

prefecture. (National Institute of Population and Social Security Research 2023) Death

counts by cause of death and age group were obtained from the vital statistics published

by the Ministry of Health, Labour and Welfare of Japan.(Ministry of Health Labour and

Welfare 2024) In line with a previous study, we categorized major causes of death using

the International Statistical Classification of Diseases and Related Health Problems 10th

Revision (ICD-10) into the top nine major cause categories (based on death counts by

cause in 2022), and aggregated the remainder into a single group, to give a total of ten

groups.(Munira, Okada, and Nishiura 2023; Ministry of Health Labour and Welfare

2024) The epidemiological data for COVID-19 were retrieved from the open-access

data provided by the Ministry of Health, Labour and Welfare. (Ministry of Health

Labour and Welfare 2023)

calculation of period life table

For subsequent use for age- and cause-specific decomposition of life expectancy

gaps, we re-calculated period life tables from 2000 to 2022 for the whole of Japan and

for all prefectures as described before. (Munira, Okada, and Nishiura 2023) We

obtained age group-specific mortality m_x using death counts and exposure-to-risk

population in each age group x. Using m_x and a_x, the average length of time to death in

deceased individuals in age group x, we calculated q_x, the probability of death in age

group x as:

114
$$q_x = \begin{cases} \dfrac{m_x\, w_x}{1 + (w_x - a_x)\, m_x}, & x = 0, 1\text{–}4, 5\text{–}9, \ldots 95\text{–}99, \\ 1, & x = 100+, \end{cases}$$

115   where w_x is the time interval of age group x. (Woolf, Masters, and Aron 2022) Starting

116   from an initial population

117
$$l_0 = 100{,}000,$$

118   l_x can be obtained by iteratively applying the formula:

119
$$l_{x+1} = l_x(1 - q_x),$$

120 for age groups $x = 0, 1$–$4, 5$–$9, \ldots 100 +$ (in years). Using l_x and a_x values,

121
$$L_x = w_x l_{x+1} + a_x d_x = w_x l_{x+1} + a_x l_x q_x,$$

122
$$T_x = \sum_{i=x}^{100+} L_i,$$

123 where L_x is the person-years spent in age group x, $d_x = l_x q_x$ is the number of deaths in

124 age group x, and T_x is the person-years of life remaining for those in age group x. The

125 life expectancy of age group x, e_x, is then calculated as:

126
$$e_x = \frac{T_x}{l_x},$$

and the life expectancy at birth is calculated as $e_0 = T_0/l_0$.

life expectancy change and COVID-19 statistics at the prefectural level

Three COVID-19 statistics at prefectural level were used for this analysis: (i)

annual number of COVID-19 cases, (ii) annual number of person-days in intensive care

because of COVID-19, and (iii) annual number of documented deaths due to COVID-

19. Using each of the COVID-19 indicators as an explanatory variable, we used linear

regression analysis to predict the year-on-year life expectancy change as the dependent

variable for 2020–21 and 2021–22.

decomposition of annual life expectancy change by age and cause of death

In line with a recent study, we used the Arriaga method for age- and cause-

specific decomposition of life expectancy change. (Munira, Okada, and Nishiura 2023;

Arriaga 1984; Arriaga 1989) The total contribution of age group x to the life expectancy

change (in years) from year y to year $y + 1$, denoted as C_x, can be described as:

140
$$C_x = \left[\frac{l_x^y}{l_0}\left(\frac{L_x^{y+1}}{l_x^{y+1}} - \frac{L_x^y}{l_x^y}\right)\right] + \left[\frac{T_{x+1}^{y+1}}{l_0}\left(\frac{l_x^y}{l_x^{y+1}} - \frac{l_{x+1}^y}{l_{x+1}^{y+1}}\right)\right]. \qquad (1)$$

141   We then decomposed C_x into cause-specific contributions:

142
$$C_x^i = C_x\left[\frac{R_x^{i,y+1}m_x^{y+1} - R_x^{i,y}m_x^y}{m_x^{y+1} - m_x^y}\right], \qquad (2)$$

where C_x^i is the contribution of cause of death i in age group x, R_x^i is the proportion of

deaths in age group x associated with cause i, and m_x is the overall mortality rate in age

group x.

life span equality h

We used a measure of life span equality h, which was derived from life table

entropy $\bar{H}$. (Aburto et al. 2020; Keyfitz 1985; Aburto et al. 2019; Demetrius 1974) Life

table entropy $\bar{H}(t)$ is a measure of variation, or inequality, in life span at time t that is

defined as:

151
$$\bar{H}(t) = -\frac{\int_0^\infty l(x,t)\ln\big(l(x,t)\big)\,dx}{\int_0^\infty l(x,t)dx} = \frac{e^\dagger(0,t)}{e_0(t)},$$

152   where $e^\dagger(0,t)$ is the special case of:

153
$$e^{\dagger}(x,t) = -\frac{\int_x^{\infty} l(a,t)\ln\big(l(a,t)\big)\,da}{l(x,t)} = \frac{\int_x^{\infty} d(x,t)e(x,t)\,dx}{l(x,t)},$$

154   which is the life disparity, or the life expectancy loss after birth, and e_0 is the life

155   expectancy at birth. Using $\bar{H}(t)$, life span equality $h(t)$ is defined as:

156
$$h(t) = -\log\big(\bar{H}(t)\big).$$

Note that, contrary to $\bar{H}(t)$, the value of $h(t)$ is the measure of life span equality. We

used a 1×1 year life table provided by JMD to calculate $h(t)$ from 2000 to 2022 for

total, male, and female populations, and evaluated the relationship between $h(t)$ and

life expectancy at birth, $e_0(t)$, for each of these populations. (National Institute of

Population and Social Security Research 2023)

Aburto et al. (Aburto et al. 2020) described the variation of $h(t)$ over time as:

163
$$\frac{\partial h}{\partial t} = -\frac{\frac{\partial \bar{H}}{\partial t}}{\bar{H}} = \int_0^{\infty} w(x,t)W_h(x,t)\rho(x,t)\,dx,$$

164   where

165
$$\rho(x,t) = -\frac{\frac{\partial \mu(x,t)}{\partial t}}{\mu(x,t)} = -\frac{\partial}{\partial t}\log\big(\mu(x,t)\big)$$

166   is the mortality improvement in age x over time,

167
$$w(x,t) = \mu(x,t)l(x,t)e(x,t) = d(x,t)e(x,t)$$

168   is the weight of the contribution of $\rho(x,t)$ to life expectancy change in age x, and

169
$$W_h(x,t) = \frac{1}{e_0} - \frac{1}{e^\dagger(0,t)}\left(H(x,t) + \bar{H}(x,t) - 1\right)$$

170
$$= \frac{1}{e_0} - \frac{1}{e^\dagger(0,t)}\left(\int_0^x \mu(x,t)dx + \frac{e^\dagger(x,t)}{e(x,t)} - 1\right).$$

Thus, $w(x,t)W_h(x,t)$ can be considered as the weight, or sensitivity, of $h(t)$ to $\rho(x,t)$

at age x. We calculated $w(x,t)W_h(x,t)$ and the threshold age a^H that satisfies

$W_h(a^H,t) = 0$ for $t = 2000, 2001, \ldots, 2022$. These results were compared with year-

on-year mortality improvement, i.e., $r(x,t) = \log\big(\mu(a,t)\big) - \log\big(\mu(a,t+1)\big)$, which

is analogous to $\rho(x,t)$ as described above. We calculated the values such as $h(t)$, $\bar{H}(t)$,

and a^H in a discretized manner regarding ages, which has been previously described

elsewhere. (Aburto et al. 2020; Aburto et al. 2019)

Software

All analyses used R version 4.2.2.(R Core Team 2023)

Results

The life expectancy at birth in Japan for the total, male, and female populations

from 2019–2022 is shown in Supplementary Table 1. These results were based on

abridged life tables that we re-calculated for use in Arriaga decomposition, but which

are almost identical to results provided by JMD. The life expectancy of the total

population decreased by 0.49 years, from 84.59 to 84.10 from 2021–22. A decrease in

life expectancy was also seen from 2020–21 of 0.15 years (from 84.74 to 84.59 years).

However, the magnitude of the shortening was greater in 2021–22. The shortening of

life expectancy at birth for both male and female populations also increased from 2021–

22, by 0.43 years for men (from 81.49 to 81.06 years) and 0.50 years for women (from

87.62 to 87.12 years).

Figure 1 shows life expectancy changes in the total population by prefecture in

2019–20, 2020–21, and 2021–22. Following the drastic change from an overall

increasing trend in 2019–20 to a sharply decreasing trend in 2020–21, all but one

prefecture saw a decline in life expectancy from 2021–22. In 2022, the greatest decrease

in life expectancy was seen in Iwate (1.00 years), and the only prefecture where life

expectancy continued to increase was Nagasaki (0.05 years). The prefecture-level life

expectancy changes of the male and female populations were largely consistent with

that for the total population (for the details, see Supplementary Data).

Figure 2 shows the correlation between reported COVID-19 burden and life

expectancy changes at the prefectural level. Combined with the linear regression results

shown in Table 1, there was no obvious correlation between annual reported cases,

person-days in intensive care, and death due to COVID-19 in 2021–22. However, this

was contrary to the findings from 2020–21.

Figure 3 shows the results of the Arriaga decomposition of life expectancy

change by age groups and major causes of death. An aggregated summary by age

groups and causes of death is shown in Supplementary Figures 1 and 2. There was a

clear negative contribution among the older population in 2020–21, and this negative

contribution was even bigger in 2021–22. The age range of the group contributing to the

reduction also widened in 2021–22 to as low as 30–34 years.

Figure 3 also shows the contributions of major causes of death by age groups.

The negative contribution of COVID-19 among the older population expanded

substantially in 2021–22. The total contribution by all ages grew from −0.095 years in

2020–21 to −0.131 years in 2021–22. In addition to COVID-19, the negative

contribution of cardiovascular causes also grew considerably in 2021–22, especially

among those over 50 years old. The total contribution of cardiovascular death was

−0.091 years in 2022, which was a consistent and substantial reduction compared with

+0.073 years in 2020 and −0.003 years in 2021. The negative contribution of "other"

causes (the remaining causes of death beyond the top nine major categories) also

increased substantially in 2021–22 among the population over 50 years old, with a total

of −0.139 years across all age groups. There was a clear decrease in the contribution of

respiratory and neoplastic disorders, and other causes from 2020–21 to 2021–22 (see

Supplementary Data for detailed results). Results from the decomposition analysis for

the male and female populations were similar to that of the total population

(Supplementary Data and Supplementary Figures 3 and 4).

226   The values of $h(t)$ as an indicator of life span equality for the total population

from 2000 to 2022 are shown in Figure 4. Panel (A) shows that h largely increased

consistently up to 2019, except in 2011 when an exceptional number of casualties

occurred due to the earthquake and tsunami that hit eastern Japan. That increasing trend

was halted in 2020 when the COVID-19 pandemic started, but has resumed since 2021.

The values of $h(t)$ for the female and male populations showed very similar patterns to

those for the total population (Supplementary Figures 5 and 6). Panel (B) in Figure 4

shows the relationship between $h(t)$ and life expectancy at birth from 2000 to 2022. A

decrease in $h(t)$ was seen in 2020 for the first time since 2011, and was followed by an

increase in 2021 and 2022 despite the shortening of life expectancy at birth.

236   To see how the overall dynamics of $h(t)$ from 2020 to 2022 can be explained

by mortality improvements by age for this period (in relation to a^H), we calculated

curves of $w(x,t)W_h(x,t)$ across ages for 2021 and 2022. (Figure 5A) We also

evaluated the year-on-year mortality improvement $r(x, t)$ from 2020 to 2022 for the

total population (Figure B). As in panel A of Figure 5, the curves of $w(x, t)W_h(x, t)$ for

2021 and 2022 for the total population were very similar, although there was a slight

shift toward the younger ages in the negative part of the curve for the older population.

As for $r(x, t)$, $r(x, 2020)$ above $x = a^H$ lay in the positive range, whereas $r(x, 2021)$

and $r(x, 2022)$ mostly lay in the negative range for the age range as seen in panel B of

Figure 5. For ages younger than $x = a^H$, the signs of $r(x, 2020)$, $r(x, 2021)$, and

$r(x, 2022)$ were inconsistent across different ages, suggesting that increased mortality

among those older than a^H clearly contributed to the increase of $h(t)$ in 2021 and 2022

(see Supplementary Figures 6 and 7 for results on the female and male populations).

Discussion

250   Our study showed the pattern of deaths in Japan during the COVID-19

epidemic (up to 2022) through demographic information. The main finding was the

growing impact of the older population and cardiovascular deaths on the shortening of

life expectancy, which was considerable from 2021 to 2022. The lack of significant

correlations between life expectancy change and epidemiological indicators of the

COVID-19 burden from 2022 is also a concern. This finding may be linked to the low

detection of COVID-19 cases and associated deaths, which is supported by our results

about the age- and cause-specific contributions to life expectancy change. The

increasing trend in life span equality despite the life expectancy shortening may also be

related to the substantial increase in mortality among the older population.

There were two key findings from our study. The first was that all age groups

over 30 years old contributed to the shortening of life expectancy in 2022, as shown in

Figure 3 and Supplementary Figure 1. However, compared with the overall shortening

attributed to age groups over 50 in 2021, the negative impact was more diffuse across

ages. This finding is similar to what was observed in 2020–21 in countries in Eastern

Europe, though the underlying situations in these countries, such as types of circulating

SARS-CoV-2 variants, vaccine coverage, and healthcare situations, would have been

quite different from that in Japan from 2021–22. (Schöley et al. 2022) In Japan, the

population-wide vaccine coverage of the second dose of mRNA vaccines (BNT162b2

[Pfizer/BioNTech] and mRNA-1273 [Moderna] vaccines) was around 80% by the end

of 2021, and the coverage of the third dose also increased from around 15% at the end

of 2021 to 68% by the end of 2022. (Cabinet Secretariat of the Japanese Government

2024) Despite this high vaccination rate, we found substantial mortality caused by

COVID-19 in Japan among wider age groups in 2022. This was not fully captured by

COVID-19 statistics, as seen in our prefectural analyses (Figure 2 and Table 1).

Another key finding was the substantial growth in the negative contribution of

cardiovascular disorders to life expectancy shortening, especially among populations

over 50 years old (Figure 3 and Supplementary Figure 2). This was not surprising,

because published studies have shown an elevated risk of cardiovascular diseases

associated with COVID-19. (Knight et al. 2022; Raisi-Estabragh et al. 2022; Lee et al.

2023; Burn et al. 2022) However, to our knowledge, our study is the first to have

quantified the magnitude of life expectancy shortening in Japan caused by

cardiovascular deaths in 2022. The negative change in contributions by respiratory

causes from 2021 to 2022 and the consistently negative trend in contributions by

neoplastic disorders since 2020 are also of note. In addition to COVID-19-associated

conditions, these findings may be attributable to an array of factors including changes in

hospital attendance. (Munira, Okada, and Nishiura 2023) There is a gap between these

findings and the global and regional cause-specific contributions to life expectancy

change from 2019–21. (Naghavi et al. 2024) Further update on this issue is warranted to

evaluate changes in life expectancy change by causes of death. The increase in the

contribution of remaining causes of death is mostly explained by the increase in deaths

due to senility, which increased by around 20,000 in 2021 and 27,000 in 2022.

(Ministry of Health Labour and Welfare 2024)

The changes in life span equality during the COVID-19 pandemic were also of

note. Our result highlights the undesirable increase in life span equality despite the

shortening of life expectancy at birth. This was in line with the substantial negative

contribution by the older population to life expectancy changes in the same period,

highlighted by the Arriaga decomposition results. These findings add to demographic

case studies on the historical relationship between life expectancy and life span equality.

(Aburto et al. 2020; Colchero et al. 2016)

Our study had some limitations. First, we could not examine the relationship

between COVID-19 and other causes of death in detail at the prefectural level, because

data on prefectural death count stratified by age and cause of death are not openly

accessible. Detailed analysis of prefectural data would have provided insights on

geographic heterogeneity, and we hope to explore this in future. Second, we ignored

geographic and temporal variation in the ascertainment bias for COVID-19 statistics.

We sufficiently met our key focus to be confident about the true mortality burden of

COVID-19, but these factors could have biased our analysis of the relationship between

prefectural COVID-19 statistics and life expectancy change. Third, we did not consider

the fluctuation in the coverage of death registrations in Japan from 2019–22. However,

it is unlikely that we missed a large proportion of deaths that would substantially affect

our results, because the completeness of death registration is reported to be 90–99% in

Japan. (United Nations Statistics Division 2023)

In conclusion, our demographic analysis showed the impact of the COVID-19

epidemic up to 2022, when the epidemic grew substantially larger. The demographic

burden of the pandemic increased more in 2022 than in 2021 or before, but the COVID-

19 burden reported by epidemiological surveillance failed to capture this trend. This is

probably due to both the shrinking coverage of epidemiological surveillance and the

growing impact of COVID-19-associated deaths caused by complications such as

cardiovascular disorders. We also showed an undesirable increase in life span equality

due to disproportionately higher mortality among older people. Our study therefore

provides valuable insights into the mortality impact of the COVID-19 epidemic in

Japan, which can now only be captured by indirect measures such as demographic

analysis in the absence of meticulous epidemiological surveillance.

4.   Data availability: We used openly accessible COVID-19 statistics from the website

of the Ministry of Health, Labour or Welfare, and life tables and related statistics

from the website of National Institute of Population and Social Security Research.

The supplementary files include the datasets used in this study. None of the data used

in the present study contained personally identifiable information.

5.   Ethical declarations: Ethical approval was not required because none of the data used

in this study included any personally identifiable information.

6.   We thank Melissa Leffler, MBA, of Edanz (https://jp.edanz.com/ac) for editing a

draft of this manuscript.

Appendixes: The online appendix is available for this paper.

514   **Table 1. Life expectancy change and COVID-19 statistics in Japan: summary of**
515   **linear regression analysis.**
516   *CI, confidence interval
517
518

519 **Figure 1. Life expectancy changes from 2019–20, 2020–21, and 2021–22 by**
520 **prefecture in Japan.**
521 Changes from (A) 2019–20, (B) 2020–21, and (C) 2021–22 are shown. In each panel,
522 bars in blue show positive changes, and red bars show negative changes. Prefectures are
523 shown in ascending order by life expectancy change in 2021–22.
524
Figure 2. Correlation between life expectancy changes and COVID-19 burden
from official statistics in Japan.
Correlation between life expectancy changes and the reported numbers of (A) annual
COVID-19 cases, (B) person-days in intensive care due to COVID-19, and (C) deaths
due to COVID-19 are shown. The variables on the x-axis are log-scaled in all panels. In
each panel, individual prefectures are shown as black triangles for 2020–21 data, or red
dots for 2021–22 data. The horizontal dashed line corresponds to "no year-on-year life
expectancy change".
533
Figure 3. Arriaga decomposition of life expectancy change by major cause of death
and age group, for the total population of Japan.
Decomposed contribution by age for (A) 2019–20, (B) 2020–21, (C) 2021–22 are
shown in each panel. The key to the colors of bars for each major cause are shown in
the panel below the plots. Bars representing major causes with a positive contribution to
life expectancy are stacked on the right-hand side, and those making negative
contributions are stacked on the left-hand side.
541
542 **Figure 4. The trend in life span equality from 2000 to 2022, for the total population**
543 **of Japan.**
544 Panel (A) shows the dynamics of life span equality by time from 2000 to 2022. Panel
545 (B) shows the same dynamics in relation to life expectancy for the same period, and the
546 years corresponding to the red dots are noted within the figure.
547
Figure 5. Weight of change in life span equality and mortality improvement by age
in Japan, total population.
Panel (A) shows the weight $w(x,t)W_h(x,t)$ for $t = 2022$ (solid blue line) and $t =$
2021 (dashed red line). Panel (B) describes the year-on-year mortality improvement
$r(x,t) = \log(\mu(a,t)) - \log(\mu(a,t+1))$ for $t = 2020$ (red), $t = 2021$ (green), and
$t = 2022$ (blue). Vertical dashed lines in both panels represent the threshold age $a^H =$
84.10 for 2022.

(A) Trend of h, 2000-22

(B) Life Expectancy at Birth and h, 2000-22

(A) 2019-20   **(B) 2020-21**   **(C) 2021-22**

Cause of Death: Neoplastic, Cardiovascular, Respiratory, External, Nervous, Digestive, Genitourinary or Renal, COVID-19, Mental, Others

Life expectancy changes (years) and reported COVID-19 burden by prefecture

Life expectancy changes (years) by prefecture, Total Population

(A) 2019-20 (B) 2020-21 (C) 2021-22
