Abstract

Objective

To assess the impact of Public-Private Mix (PPM) models for Tuberculosis (TB) diagnosis and treatment on health, process, and system outcomes within urban contexts of least developed, low Income, and lower-middle-income countries and territories (LMICs).

Design

Systematic review.

Study selection

Ten electronic databases and research repositories, covering published and grey literature were searched on 15 August 2022. All primary studies on PPM models delivering TB services in urban health sectors of eligible countries were included. There were no restrictions applied by type of outcome measurement, publication date, or language.

Data extraction and synthesis

Data were extracted on COVIDENCE and quality appraisals were carried out using the Mixed Methods Appraisal Tool (MMAT). Narrative synthesis was carried out by tabulating studies according to PPM model types (direct or interface), and assessing their performance on TB health, process (including cost-effectiveness) and system outcomes.

Results

Of the 55 included studies, covering quantitative (n=41), qualitative (n=5), and mixed-method (n=9) designs, the majority were from South-East Asia (n=36). PPM models had overall positive results on TB treatment outcomes, access and coverage, and value for money. They also promoted and improved TB health workers' skills and service delivery. Most outcomes tended to favour interface models, albeit with considerable heterogeneity. Inconsistent implementation of NTP guidelines, uncoordinated referrals, and lack of trust among partners were identified as areas of improvement. Evidence was lacking on involvement of informal providers within PPM models.

Conclusions

PPM models can be effective and cost-effective for TB care in urban LMIC contexts, particularly when levels of mistrust between public and private sectors are addressed through principles of equal partnership. The evidence indicates that this may be more achievable when an interface organisation manages the partnership.

Study registration

PROSPERO CRD42021289509.

Key messages

What is already known on this topic?

- Although previous reviews have concluded overall improvements in Tuberculosis (TB) service outcomes with Public-Private Mix (PPM) implementation, they did not explicitly focus on urban contexts. Given the rate of urbanisation in low- and middle-income countries (LMICs) and the proliferation of PPs in urban areas, an up-to-date synthesis of the urban-specific evidence is needed for policy makers to design effective PPMs.

What this study adds

- Following recommended guidelines for conducting systematic reviews, we have narratively synthesised the evidence on the impact of TB-PPM models across health, process, and system outcomes within urban contexts of LMICs.
- The implemented models appear cost-effective form the societal perspective and contribute to better TB treatment outcomes, and increased access and coverage. They also consistently promote TB health workers' skills and service delivery. Mistrust between public and private sectors can be addressed through regular communications built on principles of equal partnership.
- Although most results tend to favour models managed by interface organisations, the high heterogeneity and poor quality-scores of reporting studies must be considered.

How this study might affect research, practice, or policy

- This context-specific mixed-methods systematic review supports the implementation of PPM models for TB care in cities in LMICs. Providing decision-makers with evidence on the best design of PPM models is, however, less straightforward.
- Our review supports the need for more studies assessing different PPM model types, as well as clearer and more standard reporting of models and their performances.
- Very few studies mentioned the inclusion of informal providers in PPM-TB models. These providers have an important role in providing healthcare for vulnerable urban populations in the LMIC contexts. This gap must be addressed in future discussions and planning of TB-PPM models.

Introduction

Tuberculosis (TB) remains a major global health problem despite being preventable and treatable. According to the World Health Organization (WHO), in 2022, there were 10.6 million cases and 1.6 million deaths due to TB world over (1). The impacts of COVID-19 have led to increases in TB deaths for the first time in over a decade (1). Severe disruptions in routine TB care and services in many countries have set back progress towards achieving the WHO End TB Strategy goals of reducing TB deaths and incidence (2, 3). This is to the extent that meeting the Sustainable Development Goal of ending the TB epidemic by 2030 now seems unlikely (4, 5). Many countries also face profound economic and health losses due to the additional TB burden (5).

If progress is to be made towards the global goal of eradicating TB, expanding access to TB diagnosis and treatment services is clearly a priority action (6). Between 2015 and 2020, there were an estimated 3 to 4 million 'missing people with TB.' This refers to the difference between cases reported in national data and estimates of TB prevalence. These 'missing people' are assumed to have been treated in the private sector (1). It is not surprising, therefore, that a key priority for the Global Stop TB Partnership and the WHO is to scale up public-private mix (PPM) models, with a specific focus on improving TB care and data reporting in the private health sector (6).

Nowhere is the need to partner with the private sector clearer than in cities in low- and middle-income countries (LMICs). Rapidly growing urban populations have outstripped the capacity of meagre existing public services to meet healthcare demands (7). Studies have consistently shown that city dwellers, particularly the poorest, rely on a plethora of private providers (PPs) (8, 9). This is particularly true of TB, which is fuelled by the very determinants that are prevalent in poor urban neighbourhoods, such as overcrowding, poor nutrition, and high tobacco use (10). In addition, the private sector, characterised by limited regulation and widely available over-the-counter anti-TB drugs, tends to be the most common first point of contact for people with TB (11, 12). This combination of high vulnerability to TB and easy access to PPs for treatment underlines the need for city governments and national TB programmes (NTPs) to find ways of harnessing the private sector to provide effective TB diagnosis and care in urban areas in LMICs.

PPM models are a well-recognised and recommended mechanism to address these challenges and improve TB treatment outcomes; previous reviews have concluded overall improvements in TB service outcomes, especially in resource-limited areas (13-15). However, the reviews did not explicitly focus on urban contexts, which is key to address, given the rapid urbanisation and proliferation of PPs in urban areas and the need for policy makers to understand how to design PPMs for urban contexts (16). We, therefore, aimed to describe and investigate the impact of existing PPM models for TB diagnosis and treatment on health, process, and system outcomes in urban health systems in LMICs.

Methods

This review was developed as part of the CHORUS Research Programme Consortium which aims to develop and test ways to improve the health of the poorest urban residents and build research capacity in LMICs. This is a collaborative study developed by representatives from the CHORUS partner organisations in the UK, Nepal, Bangladesh, Ghana, and Nigeria.

Our report follows the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) guidelines (17) (Appendix 1). The review protocol was registered on PROSPERO (CRD42021289509) (18) and published (19).

Search strategy

We searched the following ten electronic databases and research repositories, covering published and grey literature on 15 August 2022: EMBASE, MEDLINE, Health Management Information Consortium (HMIC), Social Sciences Citation Index (SSCI), Science Citation Index (SCI), Emerging Sources Citation Index (ESCI), CENTRAL, Database of Disability and Inclusion Information Resources, WHO Library Database (WHOLIS) and 3ie. The search strategy consisted of two main facets, namely, PPM models and the countries or regions of interest (see Appendix 2 for details). No language or date restrictions were applied. In addition, reference lists of relevant systematic reviews were checked to identify any additional research, alongside screening of references and forward citations of included studies. Retrieved records were de-duplicated in EndNote and uploaded to COVIDENCE (www.covidence.org) for further evaluation.

Inclusion criteria and study selection

We included all primary studies examining PPM models delivering TB services in urban health sectors of the 2021 World Bank-defined (20) least-developed, low-income, and lower-middle-income countries and territories. PPM models were defined as long-term (not one-off events), formal or informal arrangements between the public and private sectors, while the term 'urban' referred to all semi-urban, peri-urban, suburban, and urban slum and non-slum areas in eligible countries. Studies that included urban and rural areas were eligible only if urban-specific results were separately reported (see Appendix 3 for detailed eligibility criteria). A total of 17 reviewers were involved in the study selection process. Sets of two reviewers independently screened the studies, first by title and abstract, then by full texts; discrepancies were resolved through discussion with a third reviewer.

Data extraction and synthesis

Seventeen reviewers were involved in data extraction and used a pre-piloted template specifically developed for this review and uploaded to COVIDENCE. All extractions were completed by a single reviewer and checked by a second reviewer. Quality appraisals were carried out using the Mixed Methods Appraisal Tool (MMAT) (21), covering mixed-methods, qualitative and quantitative study designs. Extraction items included publication details, PPM partners, their roles as previously defined (22) (stewardship/ support/ service provision/ monitoring/ financing), study characteristics and sample size, TB interventions provided by the PPM, reported outcomes related to health (TB treatment outcomes), process (indicators of access, coverage, utilisation, cost, etc.) and WHO-defined (23) system building blocks (service delivery, health workforce, information, equipment, financing, governance). The authors of the included studies were not contacted for any additional data. During the extraction and coding of the six system building blocks, the team found findings pertaining to the attitudes and behaviours of those involved in the PPM and the social and organisational context. Hence, two additional themes were added.

Narrative synthesis was carried out by tabulating and summarising studies according to PPM models (i.e., whether the partnership between the public and private sectors was direct or managed through an interface agency), and reported in line with the synthesis without meta-analysis (SWiM) guidelines (Appendix 4) (24). We also assessed the performance of different PPM models on TB health, process (including cost-effectiveness) and system outcomes.

For health outcomes, we used the percentages and confidence intervals (CIs) to build forest plots (without meta-analysis) grouped by PPM models; CIs not reported in the studies were calculated using standard deviations and sample sizes. Quantitative results relating to process and system outcomes were tabulated in similar groups and summarised. For studies reporting cost and cost-effectiveness, we first summarised the study perspectives (i.e., patient, provider, public sector,

societal) and outcomes (i.e., treatment success, disability-adjusted life years (DALYs) averted) reported. Details on cost calculations and reporting can be found in Appendix 5. Next, we plotted the results in a cost-effectiveness diagram.

All extracted qualitative findings were coded and grouped under the qualitative themes using Nvivo 1.7 (25). An inductive reasoning approach was adopted, with three reviewers independently coding the qualitative findings. Disagreements or discrepancies were resolved by discussion. The synthesised qualitative findings were combined with quantitative findings and reported against each building block. Finally, we conducted results-based convergent synthesis to explore how the PPP models affect their outcomes.

Amendments to the protocol

Our original review covered all health conditions (19). However, given the large number of studies on TB control and the comparability of outcomes reported, we amended our protocol (updated on PROSPERO) to carry out additional synthesis specifically on those papers reporting urban TB PPM models. The screening criteria originally excluded tertiary healthcare settings but was amended to remove this clause after piloting for 25 studies. Finally, we did not use RE-AIM (26) for qualitative analysis as originally planned, as the framework did not adequately capture the outcomes reported in the included studies.

Patient and public involvement

No patients or members of the public were involved in the conception, development, or analysis of the review. No patients were asked to advise on the interpretation or writing up of results.

Results

Our searches identified 7,346 records, from which 55 eligible studies on TB (reported in 63 publications) were included (27-89) (Figure 1). For eight studies (27, 28, 33, 34, 48, 49, 57, 58, 60, 61, 70, 71, 84, 85, 87, 88), the research was reported across two publications each, which were merged and extracted as one study (Table 1 and Appendix 6). Most studies were from the WHO South-East Asia region (n=36, 65.4%) (30, 33, 36, 37, 40-42, 45, 47, 48, 50, 51, 54-56, 59, 60, 62, 64-67, 69, 74-76, 78-84, 86, 87, 89), followed by Eastern Mediterranean (n=7, 12.7%) (32, 43, 44, 46, 72, 73, 77), Western Pacific (n=6, 10.9%) (27, 31, 35, 52, 57, 70), African (n=4, 7.3%) (38, 39, 53, 68), and American (n=1, 1.8%) (63) regions. One study reported models from across three different countries and regions (29).

We included quantitative (RCT protocol 1, RCT 1, non-randomised intervention studies with comparison 9, without comparison 19, observational 4, cost & cost-effectiveness 7), qualitative (n=5) and mixed-methods (n=9) studies. Few studies (mostly qualitative) met all the design-specific quality appraisal criteria (n=6, 10.9%), while scores for the remaining studies were distributed as follows: scores 4/5 = 9 (16.4%) studies, 3/5 = 19 (34.5%) studies, 2/5 = 8 (14.5%) studies, and 1/5 = 2 (3.6%) studies (Table 1). In the mixed-methods studies, we found no clear integration between the different study components, but the majority scored 3/5 or greater in the separate qualitative and quantitative parts. Finally, quality scores could not be assessed for one study protocol (48) and one study, which did not provide the necessary methodological details (29) (Table 1).

Characteristics of PPM models included in the review

We found two types of PPM models reported (Table 1 and Appendix 6) – those in which the public sector TB programme formed a direct partnership with the private sector (Direct models, n=24), and those in which there was an interface (Non-governmental Organisations (NGOs)/ Private hospital/

Medical or Pharmacists Associations/ Research organisations/ Public-Private Interface Agency (PPIA)) between the public and private sector partners (Interface models, n=36). In both model types, the roles of stewardship, monitoring, and support (as defined by Tabrizi et al., (22)) were mainly provided by the public sector, although support was also provided by the private sector partner more often in the interface compared to the direct models. Information regarding financing was not reported in many papers, but when it was reported, the public sector partner took on this role more often. Both sets of partners provided TB services (Appendix 6). Regarding the interventions provided, while some models focused on increasing case detection, the majority also aimed to decentralise TB treatment. A mix of outcomes (health/process/system) was reported in most studies, while some only reported results relating to one outcome category. For the RCT protocol that was included (48, 49), only details of the PPM model were extracted.

Health outcomes

Health outcomes for urban-specific populations were reported in 31 studies, comprising treatment success (n=29), unfavourable treatment outcomes such as default, failure, mortality (n=19), sputum conversion (n=3), and TB incidence (n=1).

Of the 29 studies reporting treatment success (27, 29, 31, 33, 35-37, 41, 43-45, 51-54, 56, 57, 60, 62, 65, 66, 68, 73, 75, 77, 78, 81, 83, 89), 17 (60.7%) reported rates >=85%. Figure 2 plots the estimates from 21/28 studies (for which 95% CIs were reported or could be estimated), according to PPM model type. The interface models achieved a treatment success rate close to 90% more consistently than the direct models, although given the heterogeneity of the studies, it was not possible to draw conclusions. Ten studies compared favourable and/ or unfavourable treatment outcomes (treatment success, default, failure, mortality) for PPM Directly Observed Treatment Short course (DOTS) provision with public DOTS/private non-DOTS during the study period (27, 29, 31, 37, 44, 62, 65, 68, 78, 81). The majority (8/10) reported comparable or better outcomes with the implementation of PPM models (Table 1 and Appendix 7). Regarding sputum conversion, all three studies reported increases after PPM implementation (55, 56, 66). One modelling study estimated that with 75% PPM with interface coverage, the cumulative incidence of TB would reduce by 8.5% (95% CI 4.2-15.6) over 10 years (84).

Process outcomes

Process outcomes were reported in a total of 45 studies, including access (n=10), coverage (case detection/ notification) (n=23), utilisation (n=4), awareness/ behaviour change (n=9), and improved efficiency (n=7). Further, we found studies that reported cost (n=4), cost-effectiveness (n=4), and both cost and cost-effectiveness (n=1).

Results showed an increase in access to TB diagnostic services (including GeneXpert testing) (70, 82, 86) and DOTS (37, 40, 42, 56, 60, 65, 75) with PPM implementation. Almost all studies reporting coverage (in both direct and interface models) reported an increase in case detection/ notification (up to 40% (62)) with PPM implementation, or they found higher rates in PPM compared to control settings (47, 59, 65, 72). In only one study, no increase in case detection was found (55), while in another, it was only reported as being close to national targets (37). On the other hand, we found less favourable results relating to utilisation of TB diagnostic and treatment services within the context of PPMs. TB testing based on GeneXpert (46), as well as TB-HIV testing and treatment (39, 68), appeared to be poorer in PPM compared to public settings. In one PPM model providing workplace DOTS, only 24.2% of those diagnosed with TB undertook treatment at the workplace (75).

Awareness and behaviour change among PPs (including pharmacies) were mainly reported in interface models and positively influenced by PPMs. These included greater use of sputum testing,

decreased reliance on chest X-rays, and adoption of DOTS among PPs (60, 69, 80, 82, 87). In private pharmacies, reduction in stocking and selling of anti-TB drugs, and greater referral to NTP services were noted (60, 63). Among the direct models, one cross-sectional study found that a considerable number of PPs still lacked access to DOTS guidelines (42.3%) and continued to treat TB on clinical suspicion (47.1%) (38). Nonetheless, increase in TB knowledge (32) and greater referrals to NTP services were also found among PPs after implementation of two direct PPM models (47).

Regarding the outcome 'improved efficiency', high TB treatment initiation was consistently reported across both model types (41, 52, 53, 81). Studies also reported lower loss to follow-up before treatment initiation among PPM PPs compared to non-PPM PPs (43). In one interface model which included both formal and informal PPs, consulting an informal PP first was associated with delay in diagnosis (absolute increase 22.8 days, 95% CI 6.2-39.5) and increased risk of long delays (aRR 2.4, 95% CI 1.3-4.4) (79).

Cost and cost-effectiveness studies

Among the studies reporting cost and cost-effectiveness, only one (reporting both outcomes) was based on a direct model (34), while all remaining studies evaluated interface models (54, 58, 64, 67, 78, 80, 85, 86). The cost studies looked at out-of-pocket expenses, time and income loss incurred by patients (n=2), as well as costs incurred by the PPM providers to implement the intervention (n=3). Most cost-effectiveness studies (n=4) adopted the societal perspective.

One costing study in Hyderabad, India (interface model), found lower out-of-pocket expenditures (e.g., fees, transport, diagnostic investigations, medications) and income loss (months' lost wages) for patients treated under PPM-DOTS compared to public-sector DOTS (treatment costs: I$ 7.56 vs I$ 83.16; months' lost wages: 1.4 vs 2.8) (54). Another before and after costing study from India found lower out-of-pocket expenditures for patients after implementing a direct PPM model to aiming ensure good quality TB diagnosis and treatment (I$ 130.03 vs I$ 897.80) (34). From the health system perspective (all interface models), the total cost (start-up plus one-year recurrent costs) of implementing PPM-TB varied substantially from I$ 14,227 for an intervention aiming to increase TB case detection, diagnosis, and treatment in Bandung City, Indonesia (80) to I$ 299,224 for an intervention aiming to improve the quality and coverage of TB diagnosis and treatment in Latipur City, Nepal (67). Costs to PPM provides per TB case detected was calculated to be I$ 424.42 in Patna, India (86) and I$ 836.91 in Bandung, Indonesia (80) (Appendix 8).

Amongst the cost-effectiveness studies, one reported the incremental cost-effectiveness ratio (ICER) per Disability Adjusted Life Year (DALY) averted (85), one the cost per DALY gained (58), and all others ICER per patient successfully treated (34, 64, 78). The ICER varied according to the intervention, perspective (e.g., societal, health system, patient), cost-effectiveness threshold (i.e., WHOC-CHOICE based on the Gross National Income and country-specific threshold), and comparator, falling in different quadrants of the cost-effectiveness diagram (Figure 3). Two studies with the interface model indicated that compared to separate public and private-sector DOTS, PPM-DOTS was cost-saving (more effective and less expensive) from a societal perspective (64, 78). Another cost-saving intervention from a societal standpoint was the scale-up and intensification of a direct PPM in 14 large cities in India (34). Using the WHO-CHOICE threshold, the DOTS-Plus project targeting MDR-TB was also cost-effective from a societal perspective in the Philippines (58). From the provider perspective, an interface model aiming to provide high-quality TB diagnostic tests and maximise treatment completion, presented mixed results in India. The intervention was cost-effective for all coverages in both Patna and Mumbai when adopting the WHO-CHOICE threshold.

However, when adopting a country-specific threshold, the intervention was cost-effective in Patna only when focused on improving treatment outcomes (85) (Appendix 8 and Figure 3).

System outcomes

Results pertaining to system outcomes covered health workforce (n=26), service delivery (n=12), leadership and governance (n=5), as well as the two additional qualitative themes, namely attitudes and behaviours within the system (n=7), and context (n=4).

Health Workforce

Several studies (both quantitative and qualitative) indicated positive outcomes in improving the knowledge and skills of the TB health workforce, and their active engagement (30, 32, 35, 66). Among the quantitative studies, one study reported using a 'training of trainers' approach to improve sustainability and follow-on training for the health workforce (35). The proportion of PPs receiving training ranged from 17.6% (50) to 82.8% (30) in direct models and 62.9% (80) to 100% (54) in interface models.

Findings from the qualitative studies (all but one based on interface models) presented insights from PPs on the value of the training in increasing their confidence to counsel and motivate patients to take up their referrals, also ensuring their client flow and status in society (70). Public and private sector providers both had concerns about the TB treatment knowledge and quality of care that the other sector provided. Even after training and dissemination of guidelines, some studies (55, 76, 82) found it a challenge to ensure care according to the government TB programme standards: "The government has a programme. The private practitioners have patients" (TB consultant quoted in 2014 Engel, pg. 922 (76)). Yet, training was identified as one part of the process of building trust between the two sectors (60, 74), in addition to being reassured that they would not lose clients through mechanisms such as the public sector issuing patients with back-referral letters (42, 76).

Motivation of PPs was another recurring theme within the health workforce domain. Several mechanisms which motivated PPs were identified including altruism and religion (70), improving public health (70, 86), financial compensation and feedback (86), professionalism (80), and increased legitimacy and standing in the community (40, 60). Standing in the community was particularly enhanced when the increased knowledge and improved practice of the private providers led to treatment success:

"When patients get better, they are thankful. They have trust in our pharmacies and let their friends and relatives know. So that helps build our customer base. That's one benefit for our business." (Focus group with pharmacists in Cambodia, 2012 Bell, pg. 1089 (70))

Service Delivery

All relevant studies (covering study designs and both model types) reported increases in the number of DOTS-providing centres following PPM implementation (35, 39, 44, 45, 68, 83). The inclusion of a variety of private and NGO providers within the models allowed adaptations to the standard public TB services offered. For example, in PPMs where NGOs were involved, home visits were also included to increase follow-up and conduct contact tracing thus strengthening service provision (40), while another study found more limited engagement of private facilities in TB-HIV services (39). The way services were delivered also changed with increased emphasis on counselling and advising patients to seek diagnosis and complete their treatment. This was particularly identified by PPM pharmacy owners as a key part of the services provided, although some felt that community perceptions of pharmacies as only providers of drugs undermined this role (70).

Where a PPM provided a new service, it ensured buy-in from PPs, for example in 2018 McDowell (82) and 2019 Daftary (86), where the inclusion of GeneXpert diagnostics and free chest x-rays respectively, provided care seekers with a tangible service. However, when there were gaps in vital services provided by the public sector, such as microscopy, the coordinated provision of services within the PPM would breakdown (55). While referral systems were a key mechanism for improving service delivery, several studies identified challenges such as limited feedback from the public to the private system (55, 74), or poor relationships between the private and public providers, undermining referrals to public services when needed (40). Only one study found that PPs were concerned about providing TB services due to fears of infection control (70).

Leadership and Governance

The leadership and governance findings were multifaceted and complex. Understanding clear roles and responsibilities of partners was essential, noting that individual roles could change and develop throughout the partnership. Joint working and communication were identified as important factors for TB PPMs, and time and trust required for this to happen effectively. However, "deep rooted tensions, rivalry and suspicion", (76) particularly between the public and private sector, have been a feature of PPMs. These factors, along with a lack of confidence in partners' capabilities, have resulted in a requirement to "build relations [and] trust" (55) through "sustained interactions" (37), based on clear commitments to the NTP and championing of the PPM. Building relations was fundamental given that PPM governance often required "changes in standards" (76) to promote and maintain the quality of services (including laboratory diagnosis, care, and drugs), necessitating control mechanisms in an environment of little previous trust or confidence in other stakeholders within the partnership. PPM stakeholders also required sufficient capacity (including the NTP) to contribute meaningfully and sustainably. This capacity could be strengthened through progressive, flexible learning programmes such as "Cambodia's learning-by-doing philosophy, its readiness to review and adapt policy" (71) or giving partners the opportunity to gain additional experience in management that ultimately were "relevant not only to TB control but other public health issues" (71).

Where leadership and governance were housed within NGOs or other interface organisations, the qualitative findings reported that this feature was crucial to success: "A key component of the PPP was the provision of an interface between the various partners. In our case this interface was a working group serviced by a liaison officer. The working group was a forum for potential partners to meet and plan the PPP. The commitment of the liaison officer proved key to the successful implementation of the PPP." (2005 Newell pg. 1014 (61))

Qualitative participants in one study in India (76) explored differences between direct government-led models and an interface model led by a private hospital. They found that where government leadership was seen as too strong with rigid reporting systems and supervision, and little respect for PP's decisions, the PPM models were problematic. Conversely, interface organisations, often under the leadership of a TB 'champion' (61, 76) ensured open communication and respect between public and private sectors, and were more effective.

Attitudes and behaviours within the system

Qualitative findings emphasised tensions in attitudes between public and private sectors. Where studies reported the evolution of PPMs over time, there were interesting reflections on changing nature of these attitudes, moving from distrust and suspicion particularly in relation to quality and motivation, to a greater understanding and respect (55, 60). However, building relationships took time, and this was identified as a significant barrier when PPMs followed the direct model and

leadership and coordination fell to the NTP: "The NTP lacks the time, and to a lesser extent the credibility, to do this, and it will therefore usually be necessary to find someone else to act." (2002 Hurtig, Pg. 84 (55))

Medical hierarchies were also identified as undermining the effectiveness of PPM models, with TB healthcare workers and volunteers working directly with patients and household contacts expressing their frustration at the lack of respect, calling for a shift toward recognising their pivotal role and addressing power dynamics (40, 42). In one study, NGO health workers of the same professional level as NTP supervisors reported being treated as inferior due to their non-public sector position, and this was despite an interface model where the NGO coordinated the PPM (76). Positive monitoring and support mechanisms were also emphasised for PPM success and scale-up (74, 75). Where all credit for improvements in programme outcomes was seen as being taken solely by the government this undermined the smooth running of the programme (42).

Context

The private sector demonstrated considerable heterogeneity, including informal providers, non-allopathic professionals, and a highly accessible, developed, and regulated pharmacy network. However, PPM policies tended to "[categorise] all types of private practitioners [irrespective of system of practice] under one broad group", seeing them "through the same lens of financial incentive" (2016 Salve, Pg. 631 (42)). While different categories of providers had different motivators for contributing to a PPM, they were not solely financial. Further, given that "unqualified practitioners predominate in poorer areas" (2014 Engel, Pg. 922 (76)), policymakers may feel uneasy about working with providers that legally do not exist but recognise that not doing so may result in lost opportunities. This did not go unrecognised by some practitioners who felt that "[PPM] policy has ignored the potential of alternative systems of medicine and the contribution they can bring to TB control efforts" (2016 Salve, Pg. 631 (42)). The role of external donors was explored in one study where qualitative participants highlighted the role of the leading global stakeholder in supporting programme implementation, knowledge transfer and capacity building (71). However, it was also noted that in the long-term, this proved unsustainable (55, 71).

Discussion

Principal findings of the review

In this systematic review, we summarise the impact of PPM models for TB diagnosis and treatment specifically within urban health systems in least developed, low income, and lower-middle-income countries and territories. Overall, we found a positive impact on health outcomes (treatment success, sputum conversion), access to healthcare and coverage (TB diagnostic services, case detection), and value for money (cost-saving interventions, reduced patient costs). We also found that PPM models promoted and improved TB health workers' skills and service delivery. Any differences in impact based on PPM model type (direct or interface) was less clear though. The interface models were more commonly linked with higher treatment success (close to 90%), reduced TB incidence (by 8.5%), improved awareness and behaviour change among PPs, effective communication, and mutual respect between the public and private sectors. On the other hand, we could not find any pattern of PPM models linked to costs and cost-effectiveness, as just one of ten studies on this outcome was based on a direct model.

Despite the overall positive impact of PPM TB in the urban scenario, our review also pointed out areas of improvement, particularly in the process and system outcomes. GeneXpert testing and TB/HIV co-infection testing were poorer under PPMs compared to the public sector. Qualitative

findings reported inconsistencies in the implementation of NTP guidelines, uncoordinated referrals, lack of confidence in the capabilities of partners, inappropriate power dynamics, and inefficiency of direct models when they adopted strict report systems and supervision.

Interpretation of findings

The WHO recommends PPM models for TB care where there is high utilisation of the private sector, poor quality of care, low case detection, poor treatment outcomes, and increased costs to affected families (90). In the context of LMICs, rapid urbanisation has exacerbated these problems, and our review findings indicate the contribution of PPMs in ameliorating them. Our findings are also supported by previous reviews on the topic (14, 15), although their inclusion criteria covered rural contexts as well. Similar to Lei et al., (15), our included studies were largely from Asia, followed by the African and American Regions. In contrast, whilst they classified the PPM collaborative characteristics as support, contract, and multi-partner groups, we categorised them as direct and interface models and within both model types, listed the roles for public and private sector partners (stewardship/ support/ service provision/ monitoring/ financing), as defined by Tabrizi et al (22). Based on their classification, Lei et al. (15) recommend multiple collaboration mechanisms, including multi-partner groups to ensure positive PPM performance. Although our findings similarly lean towards interface models with multiple partners, this must be interpreted with caution due to the heterogeneity of PPM schemes in terms of coverage, services provided, and outcome measures evaluated.

An earlier review by Malmborg et al. (14) assesses the degree to which the STOP TB Partnership's (91) global objectives of engaging all care providers are met through existing PPM interventions, and find inclusive evidence on reducing patient costs. Our updated searches identified ten studies reporting cost and/ or cost-effectiveness of PPM models, and findings indicate lower out-of-pocket payments and cost-saving interventions from the societal perspective, possibly due to the influence of lower patient costs despite high implementation costs. However, we found substantial differences in outcomes evaluated, types of costs included, and methodological approaches (e.g., cost-effectiveness thresholds) (Appendix 8), which likely influenced the high degree of variation in implementation costs and whether a model was cost-effective when other study perspectives were adopted. Another 2006 review by Malmborg et al. focuses on the range of PPs included in TB PPMs and conclude that existing models do not adequately cover providers who may be best suited to meet the needs of the poor and vulnerable (92). This is unfortunately still true; few studies mentioned non-allopathic PPs (30, 54, 62, 89), and even fewer reported on informal providers (42, 79), despite existing evidence that all providers can be successfully engaged in TB care with appropriate support and training (93).

Regarding system outcomes, findings from the present review somewhat align with the current evidence. The role of training in improving skills and service delivery within TB PPMs is well documented (15, 94), and challenges related to funding discontinuation and lack of regulatory mechanisms have been noted in non-TB PPMs as well (22, 95). Some recent studies have explored solutions to the system challenges identified such as inconsistent implementation of NTP guidelines, uncoordinated referrals, and lack of trust among partners. A study from Nigeria has recommended making less bulky and more precise NTP guidelines available at all levels of care, as well as training intensification for PPs to improve adherence (96). In another study, a Hub and Spoke model improved the referral system and uptake of GeneXpert testing after a coordinated engagement of private laboratories (97). In India, recognition of PPs as key stakeholders and equal partners, and formalization of partnerships enhanced transparency and trust between partners and a sense of accountability within PPM models (98).

Strengths and weaknesses

Our review analyses the impact of PPM models for TB diagnosis and treatment, focusing on urban settings in LMICs, to provide decision-makers with systematically synthesised evidence that is specific to these contexts. We excluded upper-middle-income countries, given the differences in trends of urbanisation compared to other LMIC groups (99). Our searches covered a large number of databases and grey literature resources, with no restrictions on outcome, publication date, or language. However, the following are some limitations to consider. First, more than half the studies (65%) were from South-east Asia, with other WHO regions being less represented. So, the extrapolation of our findings may be limited, particularly for South American countries with only one included study. Despite the extensive searches, studies may have been missed. Second, most studies reached a low-quality score (3 or lower), likely reflecting on the accuracy of the information provided. Third, we could not establish a clear pathway of impact according to the PPM model types (direct or interface) due to the heterogeneity of the studies. Finally, we found limited evidence on informal providers, who play an essential role in the TB cascade of care in urban LMIC contexts.

Implications of findings

Although PPM models have the ability to improve access to TB screening, diagnosis, and treatment outcomes in urban contexts, careful consideration is needed in their design due to considerable levels of mistrust between public and private sectors in most contexts. Factors such as excess control and top-down approaches from government agencies can undermine the strong partnership between public and private providers. Instead, where regular communication built on principles of equal partnership is implemented, PPM models appear to be more successful. There is also some evidence that this may be more achievable when an interface organisation manages the partnership.

Based on ten included studies, PPM interventions appear cost saving, with lower out-of-pocket payments. Nonetheless, more comparative research is needed to understand which PPM models are most cost-effective, particularly to guide the decision-making process and indicate the sustainability of interventions in resource-constrained scenarios (100). Further, Adepoju et al. (101) point out the difficulties in evaluating TB-PPM performances, given the variations in risk profiles, as well as access to providers and services across the public and private sectors in different urban contexts. In addition, we found poor methodological and reporting quality of existing studies. Following from these points, we support the need for clearer and more standard reporting of PPM models and their performances, with particular attention to the involvement of diverse PPs, including informal providers.

Conclusions

Taken together, our findings support the implementation of PPM models for TB care in urban LMIC contexts. Providing decision-makers with evidence of the best design of PPM models to deliver these positive outcomes is, however, less straightforward. Very few studies included informal providers, which is a major gap in urban LMIC contexts.

Table 1 – Summary of results (Health, Process, and System building blocks)

Study Year & Author Country (City)	Methodology (Quality score**)	Sample characteristics (Sample size)	Health outcomes	Process outcomes	System building blocks
DIRECT MODELS					
2003 Quy (a) (27) 2003 Quy (b) (28) Viet Nam (Ho Chi Minh City)	Post-only PPM DOTS compared with public DOTS (3/5)	People with presumptive TB (1,549)	TS: 59.8% (no CI) – poorer than NTP; Default: 36.8%; Failure: 0.5%; Mortality: 2.2%	Coverage: Case detection in PPM districts increased by 18.0% than previous year; decreased in control districts	NA
2004 Lonnroth* (29) Viet Nam (Ho Chi Minh City)	Post-only PPM DOTS compared with public DOTS (Could not assess)	People with presumptive TB (NR)	TS: 50.0% (no CI) – poorer than NTP	Coverage: Case detection (2000-01) increased by 18.0%	NA
2006 Krishnan (30) India (Ballabgarh)	Post-only PPM DOTS (3/5)	Allopathic and non-allopathic PPs (64)	NA	NA	Health workforce 82.8% PPs trained in RNTCP; 88.7% PPs referred cases; rates similar for allopathic and non-allopathic PPs
2008 Lagrada (31) Philippines (NR)	Nested case-control; those who completed/ did not complete treatment in PPM and public DOTS (2/5)	People with TB (394)	TS: 2003=93.0% (no CI) PPM, 65.0% public; 2004=88.0% PPM, 69.0% public; 2005=92.0% PPM, 81.0% public (higher in PPM, p<0.0001); Default: 2003=3.0% PPM, 22.0% public; 2004=2.0% PPM, 16.0% public; 2005=0% PPM, 12.0% public	NA	NA
2009 Ahmed (32) Pakistan (Thatta)	Pre-Post PPM DOTS (2/5)	PPs (50)	NA	Coverage: Case detection increased from 69.0% to 77.0%; Awareness/ behaviour: Increase in knowledge score after training	Health workforce: 23 of 50 PPs (46.0%) trained
2009 Pantoja (a) (33) 2009 Pantoja (b) (34) India (Bengaluru)	Pre-Post PPM DOTS with modelling analysis (3/5) For cost/CE, patient costs = consultation, drugs, diagnostics, transport, hospital stay, days lost from work	People with TB (overall NR; for cost/CE, 1,106 RNTCP and 32 non-RNTCP)	TS: 86.0% (no CI) for pre-PPM, 87.3% for PPM phase I, 87.9% for PPM phase II	CE: ICER per person treated successfully (A: PPM phases I&II implemented, B: phase I, C: pre-PPM): A vs. B Provider perspective: 93 (95% CI: 89–102); Societal perspective: cost-saving A vs. C Provider perspective: 69 (95% CI: 66–70); Societal perspective: cost-saving	NA
2010 Quelapio (35)	Time series; post-only	People with MDR-TB	TS (95% CI): 2000=65.0% (40.9-	NA	Health workforce: 12 master

Philippines (Manila)	PPM DOTS (4/5)	(1,294)	83.6); 2001=56.7% (45.3-67.5); 2002=60.3% (46.1-73.2); 2003=73.6% (48.5-89.2); 2004=72.9% (62.7-81.2); 2005=75.0% (67.9-81.0)		trainers, 31 trainers, 381 staff trained; Service delivery: 5 MDR-TB centres with 181 treatment sites, 3 culture sites established
2011 Lal (36) India (14 major cities)	Time series; post-only PPM DOTS (3/5)	People with TB (53,875)	TS (95% CI): 85.8% (85.5-86.1); Default: 6.7% (no CI); Failure: 2.7%; Mortality: 3.4%	Coverage: Case notification increased by 12.0%; contribution by health department 67.0%, medical colleges 16.0%, PPs 6.0%, NGOs 7.0%, others 4.0%	Health workforce: Large number of providers listed, but few underwent training after sensitisation efforts
2011 Pradhan (37) India (Pimpri Chichwad)	Mixed methods with time series (4/5) and interviews (5/5); post-only PPM DOTS compared with public DOTS	People with TB (3,347); interviews (3 programme officers, 8 HVs, 19 PPs); survey (497 PPs)	TS (95% CI): 2004=92.0% (88.0-96.0) PPM, 85.0% (80.0-88.0) public; 2005=83.0% (82.0-89.0) PPM, 86.0% (78.0-87.0) public; 2006=85.0% (80.0-88.0) PPM, 83.0% (78.0-86.0) public; 2007=88.0% (84.0-91.0) PPM, 81.0% (76.0-85.0) public; 2008=86.0% (82.0-89.0) PPM, 85.0% (80.0-89.0) public	Access: DOTS access increased; Coverage: Case detection close to national targets for most years since 1998;	Leadership/ governance: Systems developed for supervision and monitoring DOTS in private sector; ensuring referrals from all PPs remained a challenge
2013 Daboer (38) Nigeria (Plateau state)	Cross sectional; PPM DOTS only (3/5)	Private health facilities (17) and PPs (52)	NA	Awareness/ behaviour: 42 (80.8%) PPs knew of DOTS, 30 (57.7%) had access, 32 (61.5%) followed DOTS; 8 (47.1%) facilities gave ATT on clinical suspicion, 5 (29.4%) after testing, 3 (17.6%) referred cases	Health workforce: 22 (42.3%) PPs had training on DOTS strategy
2013 Daniel (39) Nigeria (Lagos)	Post-only PPM DOTS compared with public DOTS (2/5)	People with presumptive TB evaluated for TB and HIV (NR)	NA	Coverage: Private facilities notified 10.3% of TB cases; Utilisation: Proportion tested for HIV 86.2%, 53.1%, 96.5% in public, PFP and PNFP facilities; CPT 69.6%, 25%, 38.2%; ART 23.8%, 8.3% and 9.1%	Service delivery: At the end of 2011, 20 (1%) PFP and 11 (18.6%) PNFP facilities were engaged in PPM TB-HIV services
2014 Kielmann (40) India (Sunder Nagar[+])	Qualitative interviews and observations (5/5)	TB HVs (8) and programme officers (NR)	NA	Access: DOTS access increased	Health workforce; Attitude: HVs key but not valued. Attention to power relations can improve partnerships; Service delivery: home visits increased follow-up and contact tracing
2014 Subramaniyam (41)	Post-only PPM DOTS (3/5)	People with new and retreatment TB (112)	TS (95% CI): 95.1% (88.2-98.2) for new, 90.0% (no CI)	Efficiency: All people with TB initiated on treatment within 7	NA

India (Bengaluru)			retreatment TB; Default: 2.0% new TB, Failure: 1.0% new, 10.1% retreatment TB	days of diagnosis	
2016 Salve (42) India (NR)	Qualitative interviews and observations (5/5)	PPs (21, from different medical systems)	NA	Access: DOTS access increased	Attitude: PPs perceived to be crucial within PPM, but felt undervalued; Context: All types of PPs [irrespective of system of practice] grouped as one
2017 Khan (43) Pakistan (Lahore)	Post-only PPM DOTS across provider types (4/5)	People with TB (2,473)	TS (95% CI): 81.3% (78.5-83.8); Failure: 5.0% (no CI); Mortality: 3.0%; LTFU: 8.0%	Efficiency: LTFU before treatment lowest rate with PPM PPs, twice as high with other PPs	NA
2017 Qader (44) Afghanistan (Kabul)	Time series; post-only PPM DOTS compared with public DOTS (3/5)	People with TB (24,619)	TS (95% CI): 2010=52.5% (43.2-61.6); 2011=91.2% (85.8-94.7); 2012=65.5% (59.4-71.1); 2013 =69.0% (62.2-75.1); 2014=88.5% (84.9-91.3); 2015=79.6% (76.1-82.7) – higher than public (67.0%)	Coverage: Case notification rate increased from 59 to 125/100,000 (2010-15)	Service delivery: During 2009-2015, DOTS-providing centres increased from 22 to 85
2017 Reviono (45) Indonesia (Central Java)	Time series; post-only PPM DOTS (1/5)	People with TB (NR)	TS: 85.0% (no CI)	Coverage: Case detection=24,737 to 36,947 (2003-14) with fluctuations; case detection rate ranged from 13 to 61.7	Service delivery: DOTS facilities increased from 866 to 1,067
2018 Awan (46) Pakistan (Karachi)	Cross sectional; PPM DOTS and public DOTS (1/5)	People with presumptive TB (51,168)	NA	Utilisation: 'Xpert' yielded 19.3% & 12.9% cases at public and PPM sites, yield of DR-TB 6.9% & 3.3%	NA

INTERFACE MODELS (NGOs/ Private hospital/ Medical or Pharmacists Associations/ Research organisations/ PPIA)					
2001 Murthy (54) India (Chennai)	Time series; post-only PPM DOTS; compared with public DOTS for cost (4/5) For cost, patient costs = fees, diagnostics, drugs, travel, indirect costs	People with presumptive TB (2,244)	TS (95% CI): 90.0% (83.3-93.5) new, 77.0% (no CI) retreatment TB; Default: 5.0% new, 8.0% retreatment TB; Failure: 4.0% new and retreatment TB; Mortality: 2.0% new, 12.0% retreatment TB	Coverage: Case detection up from 50 to 200/100,000; Cost of treatment (mean I$): Diagnosis =37.80 PPM, 151.19 public, Treatment=7.56 PPM, 83.16 public, Income lost (months' lost wages) =1.4 PPM, 2.8 public	Health workforce: All 244 allopathic and 114 non-allopathic PPs in project area participated; 59% referred at least one patient
2002 Hurtig (55) Nepal (Kathmandu)	Mixed methods; pre-post PPM DOTS (3/5) and interviews (5/5)	Interviews with PPs (7), NGO staff (NR), NTP representatives (NR), pharmacists (49), people with TB (333)	Conversion (95% CI): 83.3% (72.8-90.4) 8 months pre-PPM; 86.8% (79.9-91.6) 8 months post-PPM	Coverage: No increase in case detection compared to before implementation	Health workforce: Little effect, despite manuals and visits; Service delivery; Leadership/ governance; Attitude; Context: Differences in capacity, motivation, needs, and environment, had implications
2003 Rangan (56) India (Mumbai)	Mixed methods with time series (3/5) and interviews (1/5); post-only PPM DOTS	People with presumptive TB (NR), PPs (NR)	Conversion: 2000=84.0% (no CI), 2001=90.0%; TS: 1999= 69.0%, 2000=81.0%, 2001=85.0%; Default: 1999=18.0%, 2000=9.0%, 2001=6.0%	Access: DOTS access increased; Coverage: 1999-2002, annualised case detection increased from 131 to 175/100,000	Health workforce: Improvement in quality of patient–provider interactions; regular patient meetings organized
2003 Tupasi (57) 2006 Tupasi (58) Philippines (Manila)	Post-only PPM DOTS (3/5) For CE: DOTS Plus vs. routine	People with MDR-TB (149)	TS (95% CI): 73.4% (62.1-82.4); Default: 11.4% (no CI); Failure: 10.1%; Mortality: 3.8%; LTFU: 1.3%	CE: ICER per DALY averted: Health system perspective=179; Societal perspective=242; DOTS Plus cost-effective considering the country's per capita gross income	Health workforce: Referrals were from PPs and private institutions in 73.2% of cases
2004 Arora (59) India (New Delhi)	Time series; post-only PPM DOTS compared with public DOTS (2/5)	People with presumptive TB (NR)	NA	Coverage: Case detection in PPM areas increased by 0.7/100,000 per month compared to control	NA
2004 Lonnroth* (29) India (New Delhi)	Post-only PPM DOTS compared with public	People with presumptive TB (NR)	TS: 81.0% (no CI) – similar to NTP	Coverage: Change in case detection (2000-01) = +36.0%	Health workforce: PPs participated from 18 nursing

	DOTS (Could not assess)				homes
2004 Lonnroth* (29) Kenya (Nairobi)	Post-only PPM DOTS (Could not assess)	People with presumptive TB (NR)	TS: 79.0% (no CI)	Coverage: No data for control areas; +61 cases in PPM districts	NA
2004 Newell (60) 2005 Newell (61) Nepal (Lalitpur municipality)	Mixed methods; pre-post PPM DOTS (post-only for health outcomes, 4/5) and interviews (4/5)	People with TB (1,328); interviews with PPs, NGO staff (NR)	TS (95% CI): 91.5% (87.7-94.3); Default: 1.0% (no CI); Failure: 2.0%; Morality: 3.0%	Access: DOTS access increased; Coverage: Case notification rate 54/100,000 (pre-PPM) to 102/100,000 (post-PPM); Awareness/ behaviour: Private non-DOTS reduced by two-thirds, pharmacies stocking by one-third	Health workforce; Attitude: PPs who participated gained from the PPM over time; Leadership/ governance: Interface between partners (working group serviced by a liaison officer) was key
2005 Ambe (62) India (Mumbai)	Post-only PPM DOTS compared with public DOTS (4/5)	People with TB (7,917)	TS (95% CI): 85.0% (84.3-86.1) RNTCP; 85.4 (82.2-88.1) PPs and NGOs; Default: 5.0% (no CI) RNTCP, 12.0% PPs, 4.0% NGOs; Failure: 4.0% RNTCP, 5.0% PPs, 4.0% for NGOs; Mortality: 5.0% RNTCP; 2.0% PPs, 1.0% NGOs	Coverage: PPM providers contributed 2,145 new cases in 2003, an increment of 40% above the 5,397 cases detected in RNTCP facilities	Health workforce: Private medical colleges, TB hospital, NGOs, and 1,018 (479 allopathic, 539 non-allopathic) PPs involved by referring cases, 187 acted as DOT providers
2005 Lambert (63) Bolivia (Cochabamba)	Pre-Post PPM DOTS (3/5)	Private pharmacies (359 for phase-I decreasing availability of TB drugs; 70 for phase-II improving referrals)	NA	Awareness/ behaviour: Pharmacies selling TB drugs reduced ($p<0.001$), increased referring (22.0 to 58.0%; $p< 0.001$); 38.0% pharmacies referred	NA
2006 Floyd (64) India (Hyderabad)	CE study; PPM DOTS with public DOTS and private non-DOTS (3/5) Perspective: Public sector, patients & attendants, PPs; Model: Multivariate uncertainty	People with TB (NR); treatment facilities data based on records and staff interviews (NR)	NA	CE: ICER per patient treated successfully: PPM vs. public DOTS by perspective – Public: cost-saving, Provider: 3 (no CI), Societal: 56 (95% CI: 1-110); PPM DOTS vs. private non-DOTS – Public: 56 (51–61), Provider: 123 (112–135), Societal: 0 (-45 to 45)	NA
2006 Floyd (64) India (New Delhi)	CE study; PPM DOTS with public DOTS and private non-DOTS (3/5) Perspective: Public sector, patients & attendants, PPs; Model: Multivariate uncertainty	People with TB (NR); treatment facilities data based on records and staff interviews (NR)	NA	CE: ICER per patient treated successfully: PPM DOTS vs. private non-DOTS – Public sector perspective: 95 (95% CI: 85-107), Provider perspective: 211 (189-236)	NA
2006 Maung (65) Myanmar (Kyaukse township)	Mixed methods with time series (4/5) and interviews (3/5); post-	People with TB (1,143); interviews with PPs, TB coordinators (NR)	TS (95% CI): 90.4% (83.1-94.8) PPs, 90.6% (84.5-94.6) intervention NTP, 85.1% (79.9-	Access: DOTS access increased; Coverage: PPs contributed 34% of cases registered in study	NA

	only PPM DOTS compared with public DOTS in intervention and control townships		89.2) control; Default: 5.3% (no CI) PPs, 1.3% NTP, 4.9% control; Failure: 0.9% PPs, 0.7% NTP, 0.8% control; Mortality: 3.5% PPs, 2.7% NTP, 7.4% control	township. Case notification increased by 85% in intervention, compared to 57% increase in control townships	
2007 Irawati (66) Indonesia (Yogyakarta)	Post-only PPM DOTS across provider types (3/5)	People with presumptive TB (NR)	Conversion: Increased in health centres by 10%; TS: Increased in health centres (14%), chest clinics (12%), hospitals (6%); Default: Dropped in chest clinics, remained steady in health centres, fluctuated in hospitals	Coverage: Provincial case notification rate was 70/100,000 (2004), a major increase from 22/100,000 (2000). Hospitals and chest clinics accounted for 51% of TB cases notified	Health workforce: By 2004, 29 of 34 (private and public) hospitals and chest clinics (550 personnel) trained
2007 Karki (67) Nepal (Kathmandu)	Costing study (4/5) Patient costs = travel and time lost; Volunteers = start-up and recurrent costs; Health facilities = Start-up and recurrent costs	People with TB (50); volunteers (503); personnel for institutional costs (509)	NA	Mean cost of TB treatment (I$): Facilities start-up=200.99, recurrent=337.31, total=538.30; Volunteer total=16.60; Patient costs=1,588.69 Total cost (I$): Facilities start-up=103,827,54, recurrent =195,396.87, total=299,224.41; Volunteer total=6,838.04	NA
2008 Chakaya (68) Kenya (Nairobi)	Time series; post-only PPM DOTS compared with public DOTS (2/5)	People with presumptive TB (NR)	TS (95% CI): 2002=82.6% (75.4-88.1) PPM, 75.4% (74.3-76.4) public; 2003=80.7% (69.9-88.4) PPM, 78.3% (76.3-80.1) public; 2004=76.1% (71.5-80.1) PPM, 81.6% (80.7-82.5) public; 2005= 85.0% (80.6-88.5) PPM, 81.1% (80.2-82.1) public; Default: 2002=8.0% (no CI) PPM; 12.0% public; 2003=9.0% PPM, 10.0% public; 2004=14.0% PPM, 8.0% public; 2005=8.0% PPM, 10.0% public; Mortality: 2002=5.0% PPM, 2.0% public; 2003=5.0% PPM, 3.0% public; 2004=4.0% PPM, 3.0% public; 2005=3.0% both	Coverage: Proportion of TB patients reported by private facilities increased from 2.9% (2002) to 9% (2004) and remained stable; Utilisation: Proportion of people with HIV-TB offered CPT and ART was respectively 61% and 37% in PPM vs. 84% and 32% in public sector	Service delivery: By end of 2006, 26 of 46 (57%) private hospitals and nursing homes were engaged
2009 Krishnan (69) India (Chennai)	Pre-Post PPM DOTS (2/5)	Allopathic PPs (600)	NA	Awareness/behaviour: PPs adopting DOTS increased ($p<0.0001$); 72.8% vs. 33.3% used sputum for diagnosis; CXR-alone	Health workforce: 600 PPs sensitised about RNTCP; 98.6% who treated TB patients reported educating patients,

				decreased to 16.0% from 45.4%; 55.2% vs. 22.6% used sputum for declaring cure; CXR alone decreased 54.8% vs. 25.3%	compared to 86% in the baseline (p<0.05)
2012 Bell (70) 2015 Bell (71) Cambodia (Phnom Penh)	Qualitative FGDs (5/5)	Pharmacy owners (54, 6 FGDs)	NA	Access: Increased access to pharmacy-initiated assessment and referral services	Health workforce: Altruism, pragmatism, professionalism influenced engagement; Service delivery: Advising patients among key services provided; Leadership/ governance: Capacity strengthening programme; Context: Role for global stakeholders
2012 Khan (72) Pakistan (Karachi)	Post-only PPM DOTS compared with public DOTS (5/5)	Attendees at private clinics and hospital (469,896)	NA	Coverage: In intervention area, TB case notification increased from 1,569 to 3,140 (2010-11) or 2·21 times (95% CI 1·93-2·53) relative to change in control area	NA
2012 Naqvi (73) Pakistan (Karachi)	Post-only PPM DOTS (2/5)	People with TB (309)	TS (95% CI): 87.0% (79.1-92.8); Default: 6.7% (no CI)	NA	Health workforce: Of 94 PPs, 73 trained in workshops; Four lab networks (10 outlets) included
2012 Zafar Ullah (a) (74) Bangladesh (Dhaka)	Mixed methods with interviews and FGDs (2/5); post-only PPM DOTS compared with public DOTS (4/5)	People with presumptive TB (19,000); interviews (12 PPs); 4 FGDs (24 PPs)	NA	Coverage: PPs contributed 36% of TB cases in project areas; by 2008, case notification rate in project areas = 94/100,000, national = 73/100,000	Health workforce; Service delivery; Attitude: 96% PPs had positive experience with support; limited feedback on referrals
2012 Zafar Ullah (b) (75) Bangladesh (Dhaka)	Mixed methods; post-only PPM DOTS (3/5) with interviews and FGDs (5/5)	People with presumptive TB (3,372); interviews (29 managers, 14 staff); 3 FGDs (24 staff)	TS: 100% (All people with TB treated at factory completed their scheduled treatment as per NTP guidelines; no CI)	Access: DOTS access increased; Utilisation: 3,372 of 69,000 workforce referred, 598 diagnosed, 145 received care	Attitude: Positive changes in knowledge, attitudes and practices of managers, workers, and health care providers on TB
2014 Engel (76) India (Hyderabad, Mumbai, Kerala state)	Qualitative interviews, observations, and document analysis (2/5)	Range of stakeholders (101)	NA	NA	Health workforce; Attitude: Challenge to ensure care according to RNTCP standards in private; Leadership/ governance; Context: Successful PPMs require organisational control practices bridging different professions
2015 Pethani (77) Pakistan (Karachi)	Post-only PPM DOTS (3/5)	People with TB (389)	TS (95% CI): 86.3% (82.3-89.5); Default: 8.7% (no CI); Failure: 0.5%; Mortality: 3.1%	NA	Health workforce: 94 PPs trained; 57.4% remained actively involved in the project
2015 Ramaiah (78)	CE study; PPM DOTS	People with TB (NR)	TS (95% CI): 87.0% (84.0-90.0)	ICER per patient successfully	NA

India (Kanchipuram)	compared with public DOTS and private non-DOTS (4/5)		PPM, 85.0% (84.0-85.0) public, 51.0% (46.0–56.0) private non-DOTS	treated PPM vs. public DOTS: Provider perspective = –21 (95% CI –44 to –3), Societal perspective = –278 (–312 to –256); PPM-DOTS vs. private non-DOTS: Provider perspective = 226 (184-292), Societal perspective = cost-saving	
2016 Bronner Murrison (79) India (Chennai)	Cross sectional; PPM DOTS only (3/5)	People with new and retreatment TB (289)	NA	Efficiency: 90% first contacted formal PP; median delay=51 days (mean 68); consulting an informal PP first associated with delay (absolute increase 22.8 days, 95% CI 6.2-39.5) and risk of delay >90 days (aRR 2.4, 95% CI 1.3-4.4)	NA
2017 Lestari (80) Indonesia (Bandung City)	Mixed methods; post-only PPM DOTS (4/5) and interviews (3/5) For cost, health system costs = recurrent and capital costs	People with presumptive TB (36); interviews (1 TB nurse, 1 programme coordinator, 2 PPs)	NA	Awareness/ behaviour: 5 PPs used mobile application; Total costs (I$): Start-up=9,258.75, Recurrent =4,968.45, Total=14,227.21, Maintenance (1-year)=1,529.85, Start-up and maintenance (1-year) =14,227.21, Cost/person with TB=395.20, per case diagnosed =836.91, per PP=1,185.60	Health workforce: 17 of 27 PPs (62.9%) participated in training; phone application installed for 12 PPs; for some PPs, referrals meant loss of clients, complicated reporting, and lack of supervision
2018 Chadha (81) India (Bengaluru)	Post-only PPM DOTS compared with public DOTS (3/5)	People with presumptive TB (364)	TS (95% CI): 55.4% (43.4-66.8), PPM, 75.0% (no CI) public; LTFU & Mortality: 35.2% & 8.1% PPM	Efficiency: Of 101 cases, most notified and initiated treatment within 15 days of diagnosis	NA
2018 McDowell (82) India (4 major cities)	Qualitative interviews (5/5)	PPs and public sector paediatric providers (55)	NA	Access/ Awareness: 'Xpert' helped raise awareness, aided in antibiotic stewardship, and reduced dependence on clinical diagnosis	Health workforce; Service delivery: Providers had confidence in results; rapid turnaround was key to accessing a public service
2019 Ananthakrishnan (83) India (Chennai)	Post-only PPM DOTS (4/5)	People with presumptive TB (2,621)	TS (95% CI): 89.4% (87.1-91.4); Failure: 0.3% (no CI); Mortality: 3.9%; LTFU: 5.3%	Coverage: 2,621 people tested; 1,232 (47.0%) diagnosed; PPM constituted about 10% of case notifications during project period	Health workforce: 227 of 466 (48.7%) PPs referred at least 1 patient; Service delivery: 13 interface centres established
2019 Arinaminpathy (84) 2021 Arinaminpathy (85)	CE study; transmission modelling with & without PPIA coverage (4/5)	People with TB under PPIA operations (NR)	TB incidence and mortality: With 75% PPIA coverage, cumulative incidence would reduce by 8.5% (95% CI 4.2-15.6) over 10 years;	CE: ICER per DALY averted for all PPIA coverages – cost-effective in Mumbai in all thresholds, in Patna for WHO-CHOICE, but not	NA

India (Mumbai, Patna)	Perspective: Provider		stronger impact on MDR-TB by 21.2% (95% CI 13.0-32.5); could reduce TB deaths by 21.7% (95% CI 10.6-35.0)	for country-specific threshold PPIA focusing on adherence – Mumbai: 30.5 (95% CI: 3.46-79.7), best value, cost-effective in all thresholds; Patna: 72.6 (29.6-157), best value, cost-effective in all thresholds. PPIA focusing on diagnosis – Mumbai: 441 (319-601), Patna: 803 (566-1120). PPIA focusing adherence and diagnosis – Mumbai: 228 (159-320), Patna: 564 (409-775)	
2019 Daftary (86) India (Patna)	Mixed methods; pre-post PPM DOTS (4/5) with interviews and FGDs (4/5)	Private pharmacies (105); 9 FGDs and interviews (83 pharmacists)	NA	Access: Increase in pharmacy-initiated assessment and referral; Coverage: Registration 62 times higher in intervention period (95% CI 54-72), diagnosis 25 times higher (95% CI 20-32), testing higher (p<0.001); Cost (I$): Per case detected=123.70	Health workforce: 81% of pharmacies actively participated in PPM, motivation through feedback and financial compensation; Service delivery: Care seekers provided free CXR
2020 Ramasamy (a) (87) 2020 Ramasamy (b) (88) India (Bengaluru)	Pre-post PPM DOTS (3/5)	Community pharmacists (149)	NA	Awareness/ behaviour: Change in TB knowledge after education was highly significant; 74.4% enrolled as DOTS providers	NA
2020 Shibu (89) India (Mumbai)	Pre-post PPM DOTS; post-only for health outcomes (5/5)	People with presumptive TB (185,897)	TS (95% CI): 78.4% (78.1-78.7)	Coverage: Annual case notification increased from 272/100,000 per year (2013) to 416/100,000 (2017)	Health workforce: 1,055 (48%) non-allopathic and 1,039 (62.8%) allopathic doctors notified at least one case

Figures

Figure 1 – PRISMA flow diagram

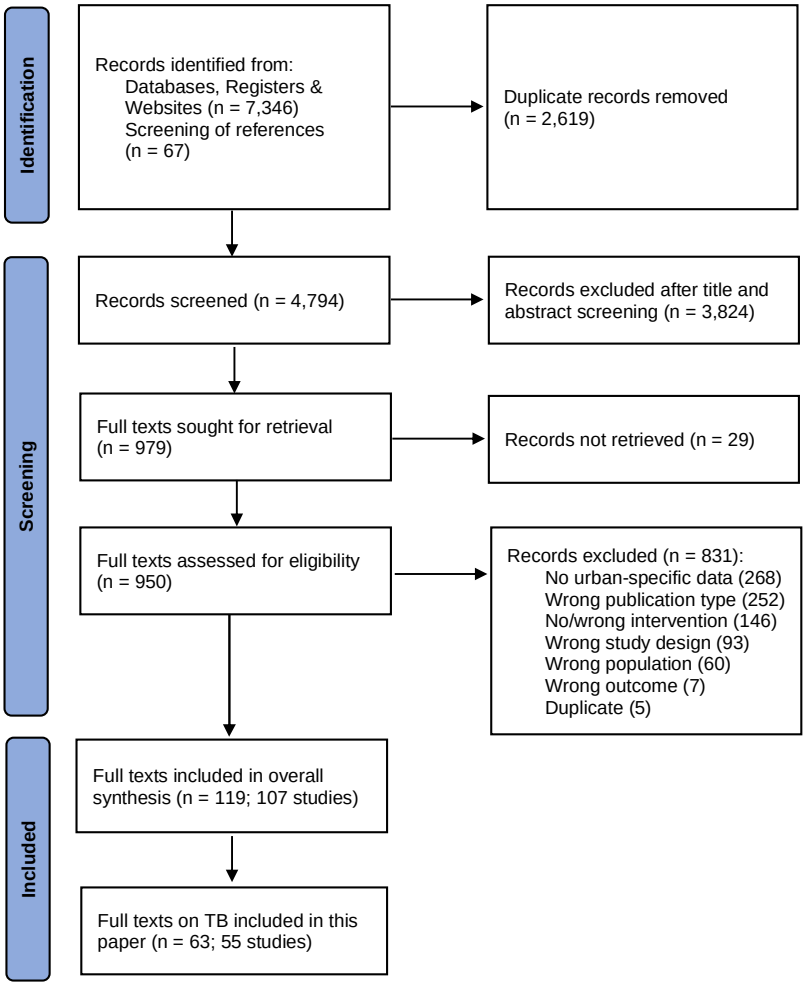

Figure 2 – Forest plot (without meta-analysis) of studies reporting TB treatment success according to PPM model type.

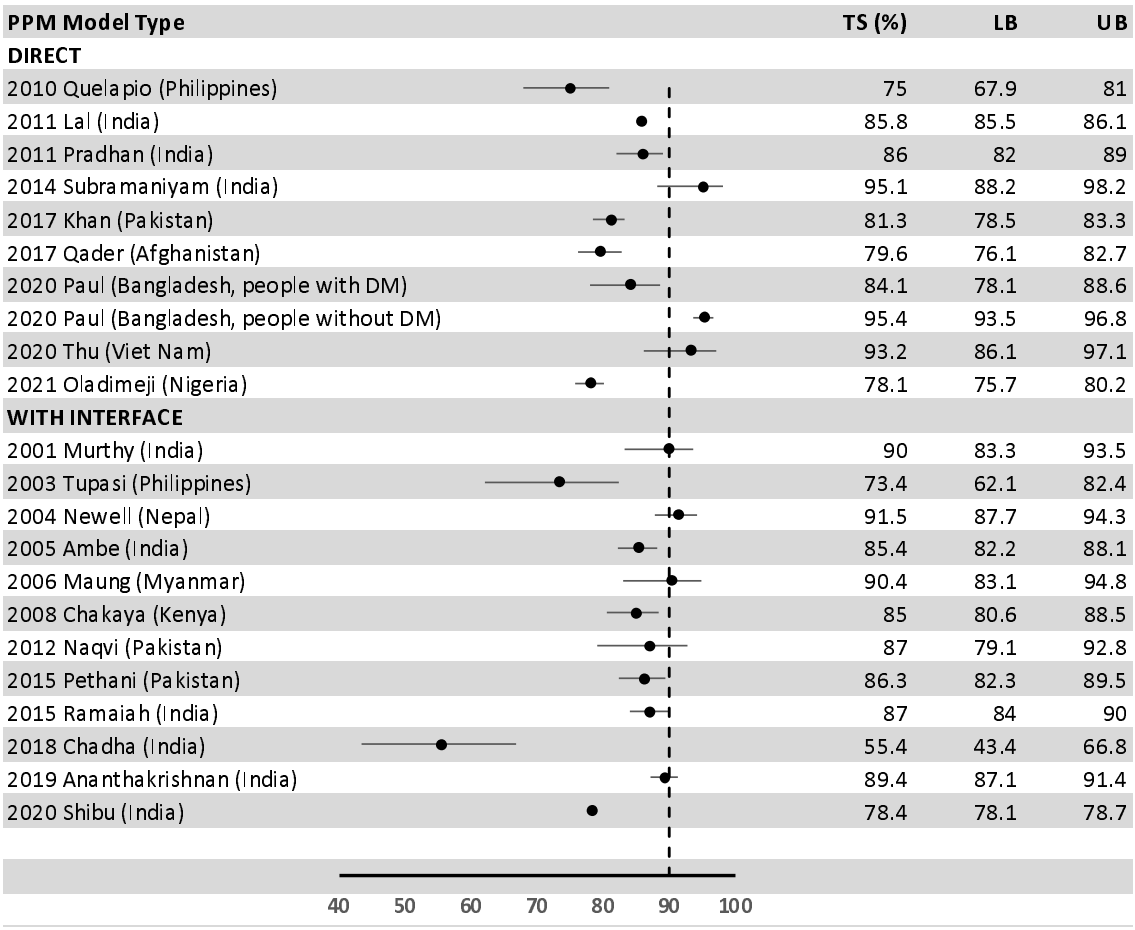

PPM Model Type	TS (%)	LB	UB
DIRECT			
2010 Quelapio (Philippines)	75	67.9	81
2011 Lal (India)	85.8	85.5	86.1
2011 Pradhan (India)	86	82	89
2014 Subramaniyam (India)	95.1	88.2	98.2
2017 Khan (Pakistan)	81.3	78.5	83.3
2017 Qader (Afghanistan)	79.6	76.1	82.7
2020 Paul (Bangladesh, people with DM)	84.1	78.1	88.6
2020 Paul (Bangladesh, people without DM)	95.4	93.5	96.8
2020 Thu (Viet Nam)	93.2	86.1	97.1
2021 Oladimeji (Nigeria)	78.1	75.7	80.2
WITH INTERFACE			
2001 Murthy (India)	90	83.3	93.5
2003 Tupasi (Philippines)	73.4	62.1	82.4
2004 Newell (Nepal)	91.5	87.7	94.3
2005 Ambe (India)	85.4	82.2	88.1
2006 Maung (Myanmar)	90.4	83.1	94.8
2008 Chakaya (Kenya)	85	80.6	88.5
2012 Naqvi (Pakistan)	87	79.1	92.8
2015 Pethani (Pakistan)	86.3	82.3	89.5
2015 Ramaiah (India)	87	84	90
2018 Chadha (India)	55.4	43.4	66.8
2019 Ananthakrishnan (India)	89.4	87.1	91.4
2020 Shibu (India)	78.4	78.1	78.7

Figure 3 – Cost-effectiveness plan for PPM TB

IV: Less effective, more costly	*ICER per patient successfully treated.* PPM-DOTS vs Public sector DOTS: Provider and societal perspective (Ramaiah and Gawde 2015)	*ICER per patient successfully treated.* • PPM-DOTS vs Public sector DOTS: provider and societal perspectives (Floyd et al. 2006) • PPM-DOTS vs private sector non-DOTS: public sector and provider perspectives (Floyd et al. 2006) • PPM-DOTS vs private sector non-DOTS: provider perspective (Ramaiah and Gawde 2015) • PPM Phase I [1] and II [2] implemented vs PPM Phase I implemented: provider perspective (Pantoja et al. 2009) • PPM Phase I and II implemented vs Pre-PPM1 [3]: Provider perspective (Pantoja et al. 2009)	*I: More effective, more costly*	***WHO-CHOICE Threshold*** [4] **COST-EFFECTIVE INTERVENTIONS** *ICER per DALYs averted.* All PPIA scenario in Patna and Mumbai: Provider perspective (Arinaminpathy et al. 2021) [5] *Cost per DALY gained.* DOTS-Plus project vs no-project: Health system and societal perspective (Tupasi et al. 2006)
III: Less effective, less costly		*ICER per patient successfully treated.* • PPM-DOTS vs Public sector DOTS: Public sector perspective (Floyd et al. 2006) • PPM-DOTS vs Private sector non-DOTS: Societal perspective (Floyd et al. 2006; Ramaiah and Gawde 2015) • PPM Phase I and II implemented vs PPM Phase I implemented: Societal perspective (Pantoja et al. 2009) • PPM Phase I and II implemented vs Pre-PPM1: Societal perspective (Pantoja et al. 2009)	*II: More effective, less costly*	***Country Specific Threshold*** [6] **NOT COST-EFFECTIVE INTERVENTIONS** *ICER per DALYs averted.* PPIA vs pre-intervention (Patna); PPIA for improving diagnostic quality (Patna and Mumbai); PPIA for improving diagnostic quality and treatment outcome (Patna): Provider perspective (Arinaminpathy et al. 2021) **COST-EFFECTIVE INTERVENTIONS** *ICER per DALYs averted.* PPIA vs pre-intervention (Mumbai); PPIA for Improving treatment outcome (Patna and Mumbai); PPIA for improving diagnostic quality and treatment outcome (Mumbai): Provider perspective (Arinaminpathy et al. 2021)

ICER= Incremental cost-effectiveness ratio; PPM-DOTS= Public-Private Partnership Directly Observed Therapy Shortcourse; PPIA= Public–Private Interface Agency; PPM= Public-Private Mix for tuberculosis care and control

[1] PPM Phase I: RNTCP started to engage with public and private medical colleges, and increased collaboration with NGOs as well as public sector entities not previously involved in the RNTCP; [2] PPM Phase II: scale up and intensify PPM in 14 large cities; [3] Pre-PPM phase: DOTS implemented almost exclusively in the facilities of the Ministry of Health; [4] Per capita Gross National Income; [5] PPIA scenarios: PPIA vs pre-intervention, PPIA for improving treatment outcome; PPIA for improving diagnostic quality; PPIA for improving diagnostic quality and treatment outcome; [6] Based on willingness to pay studies in India
