NOTE: This preprint reports new research that has not been certified by peer review and should not be used to guide clinical practice.

24 Abstract

25 Aim

Niclosamide is an established anthelmintic substance and a promising candidate for treating cancer, viral infections, and other diseases. However, its solubility in aqueous media is low, and the systemic bioavailability of the commercially available chewing tablet is poor, limiting the use of niclosamide for systemic treatment. A liquid oral formulation using polyethylene glycol 400 was developed and investigated in healthy volunteers to assess safety, tolerability, and pharmacokinetics in comparison to the marketed tablet. (ClinicalTrials.gov: NCT04644705)

33 Methods

34 The study consisted of three parts: Part A was a double-blind placebo-controlled single 35 ascending dose trial in three dose groups (200, 600, and 1600 mg) with four participants 36 receiving either the investigational niclosamide formulation or placebo (3:1) under fasted 37 and/or fed conditions. Part B was a crossover study comparing 1600 mg investigational 38 niclosamide solution with the marketed 2000 mg chewing tablet in four healthy volunteers. 39 Part C was a double-blind placebo-controlled multiple-dose trial comparing 1200 mg and 40 1600 mg (verum: placebo 4:2) in two dose groups with six subjects each, who received daily 41 doses for seven days.

42 Results

43 No serious or severe adverse events occurred. The most frequent adverse events were mild 44 to moderate gastrointestinal reactions. There was also no apparent dependence between 45 drug exposure levels (AUC, Cmax) and the severity and incidence of adverse events detectable. 46 A relevant food effect was observed with a mean AUC_{last} about 2-fold higher in fed condition 47 compared to fasted condition. In Part B, dose-normalized C_{max} and AUC_{last} were similar for 48 niclosamide solution and tablet. Absorption of niclosamide solution was highly variable. Some 49 individuals showed high absorption ($C_{max} > 2\mu g/ml$) whereas others did absorb only marginally. 50 Importantly, there was no dose linearity in the range of 200 mg - 1600 mg. No signs of 51 relevant systemic drug accumulation after multiple administrations were observed.

52 Conclusion

Overall safety and tolerability observed in healthy subjects were benign. This is also true for individual "high absorbers" ($C_{max} > 2\mu g/ml$), encouraging further research into niclosamide as a potential therapeutic agent. Galenic optimization, however, will remain challenging as evident from the observed exposure variability and non-linear PK. Non-linearity, if confirmed by additional data, might make niclosamide more suitable for multi-dose rather than high single dose regimens. The observed food effect should also be considered when further investigating systemic niclosamide exposures.

60

62 Introduction

Niclosamide is a chlorinated salicylanilide approved to treat tapeworm infections and marketed for human use since 1962 [1]. In recent years, various studies indicated that niclosamide could also be a therapeutic option for other non-infectious diseases, including malignancies, neurological diseases, metabolic diseases, and skin diseases [2, 3, 4, 5, 6, 7].

Interestingly, recent experimental data also indicate that niclosamide may be effective against SARS-CoV-2 infection through inhibition of BECN1-targeting E3 ligase SKP2 and activation of cellular autophagy processes [8]. A major hurdle in using the potentially beneficial pharmacological properties of the substance is its low aqueous solubility which limits bioavailability and systemic exposure. For COVID-19 as well as for other diseases, relevant plasma levels cannot be reached [9].

73 Currently, niclosamide (Yomesan[©]) is marketed as chewing tablets, a formulation developed 74 to hold a topical effect in the gastrointestinal tract. As a result, the bioavailability of 75 Yomesan[©] is intentionally low. Plasma level concentrations vary between 0.25– 6.0 µg/mL 76 according to the summary of product characteristics (SmPC) for a once daily administration 77 of 2 grams Yomesan[©]. This variability further limits the value of Yomesan[©] for clinical use in 78 other indications that require systemic exposure. Other formulations like niclosamide-loaded 79 nanoparticles or inhalable/intranasal formulations are being developed and tested [10, 11, 12, 80 13, 14].

We developed the drug as a drinking solution consisting of polyethyleneglycol 400 g/mol (PEG 400) as a solvent for niclosamide, aiming to increase intestinal absorption and to ensure more reproducible uptake [15, 16]. We hypothesized that the niclosamide solution would reduce

the high variability of plasma levels and increase systemic availability, making it more suitable
for the clinical treatment of systemic diseases.

86 The primary objectives of this study were to evaluate the safety, tolerability, and 87 pharmacokinetic (PK) profiles of single ascending doses (SAD) of the niclosamide solution in 88 healthy volunteers. The secondary objectives were to assess the safety, tolerability, and PK 89 profiles of multiple ascending doses (MAD) and to evaluate the PK of a single dose of the 90 niclosamide solution under fed and fasted conditions. Furthermore, the relative 91 bioavailability of the niclosamide solution compared to the marketed chewing tablet was 92 assessed. We utilized an adaptive trial design that enabled us to adjust the dose based on the 93 safety and PK data obtained throughout the study (S1 Protocol).

94 Methods

95 Study Design

This trial was a single-centre, 3-part (Parts A, B, C) randomized phase 1 trial to investigate the safety and pharmacokinetics of an investigational niclosamide solution in 28 healthy volunteers. A Data Safety Monitoring Board (DSMB) continuously monitored subject safety and decided on dose escalation in part A and initiation of parts B and C.

100 Part A was a randomized, double-blind, placebo-controlled SAD study with three consecutive

101 dose cohorts including 4 participants (verum: placebo 3:1). Furthermore, subjects enrolled in

102 cohort A3 received the drug first under fasted and later under fed conditions after a washout

103 period to investigate differences in bioavailability with regard to the fasted status.

Part B consisted of one randomized, open-label, two-sequence, two-period crossover cohort
comparing the treatment achieving the highest exposure tested to be safe and tolerable of
the niclosamide solution in part A with the marketed chewing tablets.
Part C was a randomized, double-blinded, placebo-controlled multiple ascending dose study
investigating the safety and pharmacokinetics of the niclosamide solution over a treatment
period of seven days. This part consisted of two dose groups.

111 Ethical conduct

The study was conducted at the Phase 1 Study Unit of Charite Research Organisation GmbH in Berlin, Germany following Good Clinical Practices (ICH-GCP) and the Declaration of Helsinki. An independent Ethics Committee (Landesamt für Gesundheit und Soziales [LAGeSo]) and the German competent authority (Bundesinstitut für Arzneimittel und Medizinprodukte [BfArM]) reviewed and approved the study before initiation. The study is registered with ClinicalTrials.gov, NCT04644705, and EU Clinical Trials Register, EudraCT 2020-003451-15.

118 Participants

The study was conducted from November 17, 2020, to May 3, 2021. Healthy male and female volunteers confirmed by medical history, physical examination, vital signs, and safety laboratory at screening between 18 and 45 years understanding the content of informed consent were eligible to participate in the trial. Key exclusion criteria were clinically relevant medical conditions and pregnant or lactating women. Before any screening activities, volunteers gave written informed consent to participate in the study (see S1 Protocol for the complete list of inclusion and exclusion criteria).

126 Randomization and blinding

127 Niclosamide investigational solution, chewing tablets, and placebo solution were provided by 128 Bayer AG, Germany, prepared and dispensed by an unblinded pharmacist of the clinical trial 129 supply (CTS) team at Charité Research Organization GmbH, and subsequently administered 130 by a blinded investigator. The placebo for the solution contained diluent (PEG) and 131 levomenthol as flavour. Levomenthol was also part of the niclosamide solution, thus providing 132 the same taste and volume as the placebo solution. Since the investigational solution and 133 placebo were different in colour, CTS prepared the medicinal product in identical syringes 134 covered with a non-transparent foil to sustain blinding. The administration of investigational 135 medicinal product (IMP, which could be either treatment or placebo) was randomized in a 3 136 (treatment): 1 (placebo) in part A (SAD), 4 (treatment):0 in part B (cross-over treatment) and 4 (treatment) 2 (placebo) in Part C. Eligible participants were randomized according to a 137 138 randomization list generated with SAS® 9.4 (SAS Institute Inc., USA). The randomization list 139 was not accessible by blinded staff; however, sealed emergency code break envelopes were available for the investigators in case of emergency. The IMP was provided to the investigator 140 141 by the pharmacist in a blinded manner. A sentinel dosing approach was used in part A, 142 meaning that the first subject in each cohort received an open-label administration of the 143 niclosamide solution, followed by three double-blinded subjects in each cohort. In parts A and 144 C, investigators, study staff, and participants were blinded throughout the trial.

145

146 Study Interventions

147 In part A, the IMP was administered on study day 1 under fasted conditions in cohorts A1 (200 148 mg niclosamide or placebo) and A2 (600 mg niclosamide or placebo) after safety and 149 tolerability of 200 mg have been confirmed by the DSMB. Participants were fasting for at least 150 9 hours before and at least 4 hours after IMP intake. In cohort A3 (1600 mg or placebo), the 151 IMP was first administered once in fasted condition and then, after a washout phase of 16 to 152 18 days, administered again in the same subjects under fed condition, at the same dose level. 153 Under fed condition, a high-fat, high-calorie breakfast (Guidance for Industry: Food-Effect 154 Bioavailability and Fed Bioequivalence Studies, 2001) following an overnight fast of at least 9 155 hours starting 30 minutes before treatment was consumed. Water intake was not permitted 156 from 2 hours before to 2 hours after receiving the IMP. In all parts, administration was once 157 daily (QD), orally in the morning in an upright position with 240 ml of non-sparkling water. All 158 subjects were informed about dietary/activity requirements and restrictions and adhered to 159 them.

160 Parts B and C were conducted under fed conditions, as cohort A3 showed that systemic 161 exposure of the niclosamide solution was higher and safe with prior food intake. In part B, the 162 highest tolerated and safe dose of niclosamide investigational solution in part A was 163 compared with the approved dose of 2000 mg of the marketed niclosamide chewing tablet. 164 Each subject received treatment with 1600 mg niclosamide as an oral solution and 2000 mg 165 niclosamide as a chewing tablet on study days 1 and 3 (the first day of period 2). On day 1 of 166 treatment period 1, either a single dose of the solution or the chewing tablet was 167 administered. After a one-day wash-out between each period, the other treatment variant 168 was administered on day 3.

Part C consisted of two dose groups with six subjects each. Each subject in cohort 1 received
treatment with 1200 mg niclosamide or placebo and subjects enrolled in cohort 2 received
1600 mg niclosamide or placebo once daily orally from study day 1 to 7 under fed condition.

172

173 Bioanalytical methods

174

175 In part A and part B, blood samples for measuring plasma niclosamide concentrations were 176 collected predose and at 0.5, 1.0, 1.5, 2, 4, 6, 8, 12 hours, post-dose on day 1, as well as on 177 day 2, 24 hours after dose administration. In part B, plasma levels were also measured on day 178 3 at the same timepoints. In part C, PK samples were collected at predose, and 0.5, 1.0, 1.5, 179 2, 4, 6, 8, 12 hours, and 24 h post-dose after first and last dose administration (study days 1 180 and 7), as well as predose on days 2 to 6 (trough levels). Blood was collected and centrifuged; 181 plasma was separated for bioanalytical analyses, frozen within 85 minutes of collection, and 182 stored at -80°C until shipment. BIOTEZ Berlin-Buch GmbH measured niclosamide 183 concentration by HPLC method.

184

185 Pharmacokinetic evaluation

186 Pharmacokinetics (PK) were evaluated using Phoenix WinNolin[®] software version 8.3

187 (Certara, USA). The individual and mean plasma level versus time curves were evaluated

using non-compartmental method. The AUC_{last} was calculated as the area under the plasma

189 concentration-time curve from time zero up to the time of the last quantifiable

190 concentration calculated by linear up / log down method. Food effect was evaluated using

191 non-linear mixed effect modelling.

192

193 Safety assessments

194 Safety was assessed by clinical laboratory tests, physical examinations, 12-lead 195 electrocardiograms (ECG), vital signs, and monitoring of adverse events (AEs). At screening 196 and each visit to the research unit, safety assessments were performed. Investigators 197 assessed subjects throughout the study for the occurrence of AEs and their severity and their 198 relationship to the IMP. The DSMB continuously monitored subjects' safety and made 199 decisions on dose escalation. Stopping rules included, occurrence of a related SAE in at least 200 one subject, related severe AEs in two subjects in the same cohort or relevant and confirmed 201 safety laboratory deviations in two or more subjects. Dose escalation would have been 202 stopped if plasma levels of the niclosamide solution exceed specific thresholds 203 (approximately 1.6 µg/ml) at 8 hours post-dosing in all subjects. For the high dose group of 204 1600 mg in Part C, dosing may have been discontinued if moderate to severe gastrointestinal 205 side effects occurred.

206

207 Outcomes

Primary safety outcome was monitored by the number of treatment-emergent (serious) Adverse Events (TEAE), and the recording of vital signs, ECG, and safety laboratory parameters. Secondary outcomes included the effect of food on rate and extent of absorption and various PK parameters after multiple dosing. PK profiles included the maximum plasma concentration of niclosamide (C_{max}) and the area under the plasma concentration time curve from predose

- 213 until the last detectable concentration of niclosamide (AUC_{last}). These parameters were also
- used to assess relative bioavailability of the solution as compared to the tablets.

215

216 Sample size

The number of subjects was considered adequate to investigate safety and was not based on considerations of statistical power due to the exploratory and descriptive nature of the study. In parts A and B, each dose group consisted of four subjects, with three subjects randomly assigned to receive niclosamide solution. In part C, each dose group included six subjects, with four subjects randomized to receive the solution.

222

223 Statistical methods

The primary objective was to evaluate the safety and PK of single ascending doses of the oral solution. The data obtained were descriptive since the trial was not designed for inferential statistics. A safety analysis was done in all participants who received at least one dose of study treatment. AEs and SAEs were coded according to the Medical Dictionary for Regulatory Activities (MedDRA) and recorded by system organ class (SOC) and preferred term. ECGs, Physical examinations, and clinical laboratory abnormalities were summarized.

230 Descriptive statistics were calculated for the plasma concentration of niclosamide at each 231 applicable time point specified and for the derived plasma PK parameters (C_{max} , AUC_{last}, C8h, 232 C12h, C24h, t_{max} , $t_{1/2}$). Geometric means (GM) and standard deviations (SD) were described 233 for C_{max} , AUC and $t_{1/2}$. Medians and ranges were used for T_{max} . 234 The food effect evaluation in part A and the relative bioavailability compared to the chewing

- 235 tablets in part B were performed using a linear fixed-effect model containing fixed effects for
- 236 sequence, treatment, period, and subjects within sequence for log-transformed C_{max}, and
- 237 AUC_{last}, respectively. Only subjects with evaluable data for both periods were included.
- 238 All outcomes were analyzed based on per-protocol analysis (all subjects who completed the
- 239 trial without major protocol deviations).

240 Results

241 Subjects

Twenty-eight healthy subjects were enrolled in part A (12 subjects), part B (4 subjects), and part C (12 subjects), all completed the study according to protocol. Of all participants, 21 received niclosamide and 7 received placebo (Fig 1). The demographic and clinical

characteristics of the subjects are summarised in Table 1.

248

249 Safety outcome

250 No serious or severe AEs occurred throughout the study, and no clinically relevant changes 251 from baseline were observed in any subject in physical examination, vital signs, ECGs, or 252 safety laboratory parameters. None of the stopping criteria were met in any subject during 253 the trial.

254 During the trial, 58 TEAEs occurred in 21 subjects, meaning 75% of all subjects experienced at 255 least one or more AEs. Of these, 54 were of mild intensity and four of moderate intensity. 256 Under "gastrointestinal disorders", 45 (78 %) TEAEs were grouped, with "diarrhoea" 257 (including fluid stool), (16), "nausea" (12), and "vomiting" (4) as the most frequent events. 258 For this System Organ Class (SOC), events were experienced by 14 out of 21 subjects (67%) 259 who received treatment and by 6 out of 10 (60%) subjects who received placebo. Overall, 260 seven (58%) subjects in part A, two (50%) subjects in part B and twelve (100%) subjects in part 261 C reported at least one AE. The occurrence of suspected drug-related AEs was 18 in 7 subjects 262 (58.2%) in part A, 3 AEs in 2 (50%) subjects in part B, and 28 AEs in 12 (100%) subjects in part 263 C.

- In part A, only one subject 1/9 (11%) in the treatment cohort and none in the placebo cohort
- 265 experienced a moderate TEAE "abdominal pain", which was considered to be related to the
- 266 IMP by the investigator. All other AEs were of mild intensity (Table 2).

 category; %: Percentage based on N; m: Number of events; TEAE: Treatment-emergent adverse events; Part B
 was a crossover design.

283 In part C, all subjects of the 1200 mg group, the 1600 mg group, and the placebo group 284 experienced TEAEs. Most TEAEs were mild in severity, except for three moderate TEAEs, 285 specifically two incidences of "diarrhoea" experienced in two participants in each of the 286 1200 mg group and placebo group, and "nausea" reported in one participant from the 1600 287 mg group. Three events of nausea and one event of vomiting were rated as not related, as 288 the subjects could credibly attribute them to the high-fat breakfast. A dose-dependent 289 increase in TEAEs among subjects in part C was not observed (Table 6). All subjects had at 290 least one or more events.

296 Pharmacokinetic Results

297 Plasma concentrations niclosamide solution

298 C_{max} and AUC_{last} showed a non-linear absorption behaviour of the niclosamide solution, 299 except for AUC_{last} in cohorts A1 to A2 suggesting no deviation from dose proportionality in 300 the range of 200 to 600 mg. The mean concentration-time profiles of each cohort remained 301 similar throughout the study, showing a rapid increase and decline in plasma concentration 302 (Fig 2). Variability continued to be very high across dose groups for C_{max} and AUC_{last}, especially 303 in fasting conditions and for higher doses. The highest values for C_{max} and AUC_{last} were 2.77 μ g/ml and 19.15 μ g*h/ml, respectively, and were achieved with the solution under fed conditions.

306

Fig 2. Geometric Mean Niclosamide Plasma-Concentration vs Time Curves following oral administration per cohort. (A) Single ascending doses (200 mg - Cohort A1, 600 mg - A2, 1600

309 mg - A3) under fasted conditions (A3 also in fed state). (B) 1600 mg solution and 2000 mg

tablets under fed conditions. (C) 1200 mg and 1600 mg solution over 7 days in fed state.

311

312 In the SAD part A, median T_{max} ranged from 0.5 to 1.5 h across (fasted) cohorts and trended

313 toward longer times with increasing doses. Individual plasma concentrations followed first-

order kinetics, declining exponentially over elimination phase. . Half-lives (GM) increased with

- 315 increasing dose levels, from 3.43 h for the 200 mg dose to 4.15 h for the 1600 mg dose. C_{max}
- 316 (GM) increased 2.0 -fold from A1 to A2and and only 1.3- fold from A2 to A3. AUC_{last} (GM)
- 317 levels for the same cohorts increased 3.4 -fold (A1 to A2) and 1.2- fold (A2 to A3) (Table 7).

Parameters	Cohort A1 fasted	Cohort A2 fasted	Cohort A3 fasted	Cohort A3 fed

321 Time to reach Cmax (median [range]); C8h, C12h, C24h: Plasma conc at 8, 12, 24 hrs post-dose; t1/2: Terminal

322 half-life; n: Subjects; BQL: Below quantifiable limit. Geometric mean and standard deviation presented.

323

324 Food effect

- 325 A relevant effect of food intake on the absorption of niclosamide was observed as the median
- t_{max} was prolonged under fed conditions compared to fasted conditions (4 vs. 1.5 h). $T_{1/2}$ was
- 327 only slightly higher fasted compared to fed conditions (4.77 vs. 5.28 h) (Fig 2A).
- 328 GM C_{max} was 1.2-fold higher for fed than fasting, and the GM AUC_{last} doubled for fed
- 329 compared to fasting conditions with lower variability (9.90 [1.78] vs. 4.86 [3.38] µg*h/mL)
- 330 (Table 7) suggesting a substantially increased extent of absorption when niclosamide is
- 331 administered after a high-fat, high-calorie meal.
- 332

333 <u>Relative Bioavailability of niclosamide solution</u>

- 334 In part B, the median t_{max} was 1.5 h for the chewing tablet compared with 1 h for the solution,
- in line with expectations for each formulation. $T_{1/2}$ was slightly shorter for the tablet cohort
- than the solution cohort and considerably shorter than in the Fed part A3 (Table 8). Notably,
- the variability in PK parameters was lower for the chewing tablet.

Table 8 Comparison of Niclosamide PK parameters for solution and chewing tablet formulations under Fed conditions - Part B

PK-Parameters	Niclosamide solution	Niclosamide chewing tablets
	1600 mg fed	2000 mg fed
	n=4	n=4
Cmax, μg/mL	0.78 [3.00]	0.91 [1.45]
AUClast, μg*h/mL	3.47 [2.99]	5.16 [1.22]
Cmax/D, μg/mL	0.49 [3.00]	0.45 [1.45]
AUClast/D, μg*h/mL	2.17 [2.99]	2.58 [1.22]
tmax, h	1.0 [0.5-2.0]	1.5 [1.0-4.0]
C8h, μg/mL	0.12 [2.29]	0.18 [1.88]
C12h, μg/mL	BQL	0.06 [5.44]
C24h, μg/mL	BQL	BQL
t1/2, h	3.99 [1.49]	3.66 [1.93]

341 Cmax: Max plasma concentration; AUClast: Area under plasma conc-time curve to last quantifiable conc; Cmax/D, 342 AUClast/D: Cmax, AUClast normalized to dose; tmax: Time to reach Cmax (median [range]); C8h, C12h, C24h:

343 Plasma conc at 8, 12, 24 hrs post-dose; t1/2: Terminal half-life; n: Subjects; D: Dose (1.6g solution, 2g tablet); 344 BQL: Below quantifiable limit. Geometric mean and standard deviation presented.

- 345
- 346 Dose-normalized AUC_{last} and C_{max} were comparable between niclosamide solution and
- 347 niclosamide chewing tablets (C_{max}/D 0.49 [3.00] vs. 0.45 [1.45] µg/mL per g and AUC_{last}/D 2.17
- 348 [2.99] vs. 2.58 [1.22] µg*h/mL per g) indicating that the solution did not lead to an increased
- 349 bioavailability.
- 350
- 351 Plasma concentrations multiple dosing
- 352 In the MAD part C, the GM of $t_{1/2}$ increased in dose group 1200 mg from day 1 (5.26 h) to day
- 353 7 (5.76 h). On the other hand, the GM $t_{1/2}$ in dose group 1600 mg was overall slightly shorter
- 354 than in the 1200 mg group, with 4.15 h on day 1 and 5.49 h on day 7 (Table 9).

Cmax: Max plasma concentration; AUClast: Area under plasma conc-time curve to last quantifiable conc; tmax: 358 Time to reach Cmax (median [range]); C8h, C12h, C24h: Plasma conc at 8, 12, 24 hrs post-dose; t1/2: Terminal

359 half-life; n: Subjects; BQL: Below quantifiable limit. Geometric mean and standard deviation presented.

360

362	C_{max} (GM) between day 1 (0.68 $\mu g/ml$) to day 7 (0.67 $\mu g/ml$) in dose group 1200 mg was similar
363	on both days. For dose group, 1600 mg C_{max} (GM) was higher overall than in the 1200 mg
364	group but declined between day 1 (1.39 μ g/ml) and day 7 (0.90 μ g/ml).
365	AUC _{last} (GM) had increasing trends from day 1 (2.48 μg*h/ml) to day 7 (3.97 μg*h/ml) in dose
366	group 1200 mg. In contrast, in the dose group 1600 mg, AUC _{last} (GM) decreased 47 % in the
367	same interval yet exceeded the dose group 1200 mg 3.3-fold on day 1 (8.18 $\mu g^*h/ml)$ and was
368	only slightly higher on day 7 (4.34 μ g*h/ml).
369	Mean and individual trough concentrations of niclosamide measured on days 3 to 7 were all
370	below the quantifiable limit for the 1200 mg and 1600 mg groups, suggesting no accumulation
371	after multiple dosing.
372	The high variability, the poor bioavailability and the decrease in AUC after multiple dosing
373	might all be connected to the side effects experienced from the PEG carrier solution. The
374	correlation between adverse events and pharmacokinetics was therefore further analyzed.
375	
376	Correlation between adverse events and plasma concentrations
377	From the AE summaries (Tables 4-6), after nausea, diarrhoea was the most frequent preferred
378	term for AE classification. Diarrhoea impacts intestinal passage time and might therefore
379	reduce absorption.
380	To analyze the relationship between exposure variability and diarrhoea further, we compared
381	the subjects with diarrhoea and the subjects without diarrhoea to dose-normalized C_{\max} and
382	AUC, pooling the 1600 mg groups (A3 fed/fast, B, C) and 1200 mg Part C group. We considered
383	AEs on day 1 for all groups, and additionally on day 7 for group C, because Cmax and AUC

- were only measured on these days. Groups A1 and A2 showed no diarrhoea on day 1. There
- 385 is a pattern suggesting that subjects with diarrhoea had a lower C_{max} and AUC_{last} compared to

386	subjects who did not experience diarrhoea after drug intake (Fig 3). However, even in subjects
387	without diarrhoea, variability in exposure remained high with a roughly fourfold increase
388	from lowest to highest value.

389

Fig 3. Diarrhoea Incidence vs. Dose-normalized Cmax (A) and AUC (B) in Niclosamidetreated Subjects. This figure presents the comparison of individual dose-normalized (A) Cmax
(µg/mL per g) and (B) AUC (µg/mL per g) data in relation to the incidence of diarrhoea (no
diarrhoea vs. diarrhoea) after niclosamide solution administration.

To inform the relationship between exposure and AEs, we plotted the number of any TEAE reported against a group of "high absorbers" and a group of "regular absorbers". High absorption was here arbitrarily defined as being at least 2 μ g/ml (Fig 4). Interestingly, we did not find a clear correlation between niclosamide exposure and TEAS. Two of the high absorbers did not report any adverse event and three high absorbers reported two adverse events which where all mild. Overall, the analysis suggests that number and severity of AEs is independent of the niclosamide exposure level reached in the individual.

402

403 Fig 4. TEAEs Comparison between High Absorbers (Cmax > 2µg/ml) and Regular Absorbers
 404 (Cmax < 2µg/ml). This figure compares the number of treatment-emergent adverse events
 405 (TEAEs) in high absorbers and regular absorbers after niclosamide administration, highlighting
 406 the differences in TEAE distribution between the two groups.

408 **Discussion**

409 The primary objective of this Phase 1 trial was to assess the safety and pharmacokinetics of a 410 novel niclosamide solution. The study included a single ascending dose (SAD) consecutive 411 group design (Part A) including assessment of the effect of food on oral absorption of 412 niclosamide, a crossover comparison of bioavailability with a marketed chewing tablet (Part 413 B), and a multiple ascending dose (MAD) design (Part C). Cohort A3 was repeated under fed 414 conditions to study whether food was affecting systemic exposure of the niclosamide solution. 415 The study protocol allowed for dosing in parts B and C to be performed under either fasting 416 or fed conditions, depending on the bioavailability data obtained.

To evaluate the relative bioavailability of the niclosamide solution compared with the chewing tablet, a crossover part (Part B) was performed to exclude inter-individual differences in absorption and thus minimize the variability of PK parameters. The niclosamide solution's highest tolerated and safe dose in part A was compared to the marketed chewing tablet at the highest approved dose of 2000 mg. Due to the higher exposure of niclosamide solution observed in cohort A3, the IMP was administered with prior food intake.

An MAD design (Part C) was chosen to investigate safety and PK after repeated drug administration. Since multiple gastrointestinal AEs were observed at the 1600 mg dose in the single dose parts, two different dose levels, 1600 mg, and 1200 mg, were chosen. Dosing in the 1600 mg could have been stopped if intolerable gastrointestinal AEs prevented further intake. In that case, dosing could have been continued with the 1200 mg niclosamide solution in these discontinued subjects, in addition to the four other subjects in the 1200 mg group.

In cohorts A and C, a placebo control was included that allowed differentiation between drugrelated AEs and AEs that may occur without active treatment.

In 28 healthy volunteers, the investigational niclosamide solution was reasonably welltolerated in doses up to 1600 mg, with no severe TEAEs reported. The overall frequency of suspected related TEAEs was 18 TEAEs in 7 (58.2%) subjects in part A, 3 TEAEs in 2 (50%) subjects in part B, and 28 TEAEs in 12 (100%) subjects in part C. The most common related TEAE were gastrointestinal symptoms such as diarrhoea (including liquid stool), nausea, and vomiting shortly after IMP administration. No trends were observed in hematologic and clinical chemistry parameters, vital signs, or ECG during the study.

438 TEAEs reported across the SAD and MAD parts were mild to moderate intensity. There were 439 no discontinuations, and no TEAE needed medical intervention, except for "abdominal pain" 440 in cohort A2, which was treated with oral ibuprofen. The proportion of gastrointestinal events 441 increased with increasing dose and volume of solution, with no TEAEs in cohort A1, 66% in 442 cohort A2, 100% in the fasted part of cohort A3, 67% in the fed part (2/3 subjects), 50% in 443 part B after receiving solution and 100% in both treatment groups of part C. A relationship 444 between TEAEs frequency and exposure was not found. Since subjects receiving placebo also 445 had the same proportion of AEs and the frequency of AEs was independent of AUC or C_{max}, 446 but incidence increased with solution volume, the excipient PEG 400, an osmotic agent, likely 447 led to these gastrointestinal events. This is corroborated by the fact that the volume of the 448 excipient also increases with the dose of the drug. The volume of niclosamide solution was 5 449 ml for 200 mg, 15 ml for 600 mg, 30 ml for 1200 mg, 40 ml for 1600 mg, and 20 ml in part C for the placebo. PEG-400 was used here as a solvent to increase absorption in the intestine. 450 451 However, PEG has an osmotic effect and is the basis of some laxatives used in 452 gastroenterology, known to cause GI side effects that could affect absorption [15, 17].

453

454 Comparison of C_{max} and AUC_{last} versus dose revealed a non-linear increase in exposure over 455 the dose range investigated, while deviation from dose proportionality was not evident 456 between cohort A1 (200mg) and cohort A2 (600mg). This pattern could be explained by poor 457 solubility, which could potentially limit the oral bioavailability of this niclosamide formulation 458 at higher doses. At higher oral doses, the undissolved niclosamide might precipitate in some 459 subjects. Furthermore, a positive food effect after a standard high-fat, high-calorie breakfast 460 was observed; Fed GM C_{max} and AUC_{last} were 1.2-fold and 2-fold higher for fed compared to 461 fasting conditions. Compared with fasting, the median t_{max} of mean plasma concentrations 462 was prolonged under fed conditions, with individual plasma concentrations showing a 463 delayed decline after C_{max} and measurable niclosamide plasma concentrations up to 12 hours 464 after administration. It is noted, however, that the food effect might also - at least in part -465 be explained by the fewer observed gastro-intestinal AEs in the fed as compared to the fasted 466 subjects.

467 Subsequent cohorts A3 and parts B and C were conducted under fed conditions, as the 468 systemic exposure of the niclosamide solution was increased prior to food intake.

The variability of the PK parameters remained very high in all dose groups, especially under fasting conditions and at higher doses. The high variability could partly be explained by the gastrointestinal side effects like diarrhoea or vomiting which reduce resorption.

In part A, high variability in exposure was observed with even higher variability under fasting conditions and at increasing dose levels. The geometric coefficient of variation (Geo CV) for C_{max} in Cohort A1, A2, A3 fasted, and A3 fed, was 101%, 44%, 253%, and 53% and for AUC_{last} it was 8%, 58%, 185%, and 62%, respectively. After a high-fat,/high- calorie meal, PK variability was almost 2-fold lower for this treatment speaking for a dose recommendation under fed conditions in clinical practice. Variability was also high in part B, especially for the niclosamide

solution. The Geo CV for C_{max} was 153% and 38%, and for the AUC_{last} was 152% and 20% for
the solution and chewable tablets, respectively, making the chewing tablet more favourable
for clinical use due to more predictable pharmacokinetics. In Part C, variability was less
pronounced, decreasing from day 1 to day 7, with similar values in both dose groups, with
Geo CV for C_{max} ranging from min. 20% to max. 60% and AUC_{last} ranging from min. 10% to
max. 39%.

484 Contrary to our expectations, the novel formulation did not significantly improve intestinal 485 absorption compared to the marketed chewing tablet. Data obtained from part B of our study 486 indicate that the niclosamide solution may not hold a significant advantage over the chewing 487 tablet with regard to bioavailability. However, it is important to consider that the FDA-488 standard breakfast consumed during the trial might have been excessively large, thereby also 489 influencing absorption. This sizeable, high-fat meal can independently contribute to 490 gastrointestinal side effects. Moreover, it is possible that bioavailability could be further 491 optimized by adjusting the ratio of niclosamide to PEG, specifically by reducing the amount of 492 PEG utilized, as it was likely causatively responsible for the observed gastro-intestinal side 493 effects.

Following multiple, once-daily doses of 1600 mg over 7 days, AUC_{last} was 3,3-fold and 1,1-fold higher on day 1 and 7, respectively, compared to the 1200 mg group. Exposure decreased from day 1 to day 7 in the 1600 mg group, most strikingly with AUC_{last} decreasing by 47 %. Whereas 1200 mg AUC_{last} increased by 38%. Gastrointestinal symptoms occurred more frequently with multiple dosing than single dosing of parts A and B, possibly affecting niclosamide plasma levels. Following multiple doses QD over 7 days, niclosamide showed no accumulation. 501 There is a pattern suggesting that diarrhoea after study drug ingestion results in reduced 502 absorption, as reflected by a lower C_{max} and AUC_{last} compared with subjects who did not have 503 diarrhoea after drug administration (Fig 3). The mean concentration-time profiles of each 504 cohort remained similar throughout the study, showing a rapid increase and decline in plasma 505 concentration. There were individual high absorbers (with C_{max} values > 2 μ g/ml) with the 506 highest values for C_{max} and AUC_{last} of up to 2.77 µg/ml and 19.15 µg*h/ml, respectively, 507 showing only mild TEAEs and no moderate or severe TEAEs. No clear pattern could be 508 identified by comparing the counts of TEAEs from high absorbers with those from regular 509 absorbers (Fig 4), indicating that high plasma levels of niclosamide do not result in acute 510 toxicity which might encourage further exploration of pharmacologically active niclosamide 511 exposure levels. Obviously, the small sample size of our study does not allow any firm 512 conclusions on safe exposure levels.

513 Up to now, there is only scarce public information on the pharmacokinetics of niclosamide. A 514 phase I study by M. T. Schweizer et al. of niclosamide as a chewing tablet in combination with 515 enzalutamide in men with castration-resistant prostate cancer that enrolled 3 patients in a 516 500-mg TID cohort and 2 patients in a 1000-mg TID cohort for 4 weeks showed a niclosamide 517 range for C_{max} from 0.04 to 0.18 µg/mL (Dose normalized: C_{max}/D 0.07 to 0.36 µg/mL per g), 518 for t_{max} from 1 to 6 h and for $t_{1/2}$ from 1.27 to 5.61 h [18]. We showed a C_{max}/D ranging from 519 0.13 µg/mL per g in the 1600 mg group to 4.90 µg/mL per g in the 200 mg group. Except for 520 three individuals (RND: 132 in A3 fasted, 214 in B, and 319 in C on day 1), every C_{max} was 521 higher in our study than in the aforementioned study. When only comparing the identical 522 formulation (chewing tablet), it is noticeable that in our study Part B C_{max}/D was still twice as 523 high (C_{max}/D 0.30 to 0.62 µg/mL per g) than in Schweizer et al.'s study. This could be due to 524 the high-fat breakfast. Unfortunately, in the study published previously patients were allowed to take niclosamide fasting or non-fasting, so it cannot be clearly determined whether the
high-fat breakfast resulted in the difference in PK.

527 Schweizer et al. showed that C_{max}, AUC, and t_{max} exhibited large individual variability in both 528 dose groups, which is confirmed by our study. Also, the C_{max} values determined in the study 529 including cancer patients were lower than the range of 0.25- $6.0 \,\mu$ g/ml described in the SmPC. 530 Niclosamide acts on multiple highly conserved signalling pathways including, but not limited 531 to, the inhibition of several inflammasomes [19], the inhibition of Signal transducer and 532 activator of transcription protein 3 (STAT3) [20], the upregulation of autophagy via S-phase 533 kinase-associated protein 2 (SKP2) inhibition [21], inhibition of TMEM16A [22] and the 534 inhibition of the Wnt/ β -catenin pathway [23]. Interfering with these signalling pathways could have many beneficial effects, but could also pose certain risks. Potential benefits and 535 536 risks of interfering with these pathways are described in the public domain.

537 By inhibiting inflammasomes, the immune system may be compromised, which could lead to 538 opportunistic infections caused by fungi and certain bacteria [24]. Similarly, inhibition of 539 STAT3 could lead to humoral immunodeficiency, promoting the reactivation of viruses and 540 impaired ability to fight infections [25].

541 Inhibition of SKP2 by niclosamide reduces the degradation of Beclin1, which promotes 542 autophagic flux. Although there is evidence that activation of autophagy may limit tumor 543 development, there is also suggestive evidence that inhibition of autophagy restricts the 544 growth of preexisting tumours and enhances the response to tumor therapies [26]. 545 Furthermore, Beta cells in human type 2 diabetes show signs of increased autophagic flux, 546 which may promote the loss of beta cell mass [27]. Increased autophagy could also be harmful 547 in certain cardiovascular diseases and contribute to disease progression suggesting that 548 modulations of autophagic flux need to be well balanced [28].

549 Numerous therapeutic strategies are being developed to inhibit the Wnt/ β -catenin pathway, 550 which may be effective against several malignancies [29]. Activation and overexpression of 551 this pathway are frequently observed in malignant tumours. However, the Wnt/ β -catenin 552 pathway also regulates embryonic development and tissue homeostasis in adulthood, 553 maintaining bone, hair, skin, gastrointestinal tract, liver, and lung, and is involved in 554 hematopoiesis and neurogenesis in adulthood [30, 31]. Expected adverse effects of inhibition 555 of this pathway could include, for example, wound healing disorders, bone loss or fractures, 556 hair loss, elevated liver enzymes, and anaemia.

However, none of these potential side effects were observed in our study, but they should beconsidered in future studies that might involve prolonged use of niclosamide.

559 A limitation of our study is the low number of subjects, which restricts the generalizability of 560 the PK parameters. Our study was conducted under the circumstances of the COVID-19 561 pandemic, which necessitated expedited timelines to explore potential antiviral treatments 562 and explains the lower number of subjects. Moreover, interindividual variability was high, 563 limiting the interpretation of results. Furthermore, a notable limitation is the lack of 564 pharmacodynamic and surrogate parameters, as the study was conducted in healthy 565 volunteers rather than a target patient population. Consequently, assessing the potential 566 therapeutic effect and underlying mechanisms of action of the novel formulation in treating 567 malignancies or viral infections remains challenging.

However, even with a higher number of subjects, the argument would not change. Based on the existing number of subjects, the study offers a reasonable evaluation of the niclosamide solution. The results suggest that it has not demonstrated clear benefits over the tablet form in aspects such as bioavailability, safety, tolerability, and controllability.

572 Overall, this study showed that administering the niclosamide solution up to 1600 mg for 7 573 days QD was reasonably well-tolerated and exhibited an acceptable safety profile in healthy 574 subjects. While diarrhoea and vomiting were not considered clinically relevant in healthy 575 subjects and were not otherwise of concern to the DSMB, it could likely pose patients with 576 serious conditions at risk because of exsiccosis, electrolyte disturbances, or impaired 577 absorption of essential concomitant medications; thus, the risk would outweigh the benefit. 578 Moreover, contrary to our expectations, the new formulation did not improve niclosamide 579 absorption. The variability in exposure remained high, and sufficiently higher plasma concentrations were not achieved. In fact, according to our data, the chewable tablet is 580 581 probably equally efficient to reach systemic exposure with fewer adverse effects with similar 582 exposure.

583 Conclusions

This study added to the understanding of niclosamide pharmacokinetics in humans. The tested niclosamide solution was reasonably well-tolerated, but bioavailability did not meet expectations, indicating that the niclosamide solution is not superior to treat systemic conditions compared to the established one. Consequently, the data do not support further clinical investigation of this particular niclosamide solution, but two key findings resulted and could have important implications for further clinical research with niclosamide.

590 First, individual high absorbers tolerated the study drug well, suggesting that potentially 591 pharmacologically active plasma levels of niclosamide do not lead to acute toxicity, which 592 might be relevant for potential dose escalation in subsequent studies. Secondly, a positive 593 food effect of up to 2-fold after a standardized high-fat breakfast was observed.

- 594 Potential applications for niclosamide through multiple drug mechanisms addressing multiple
- 595 pathways and drug targets show the broad spectrum of potential applications for this drug
- and underline the need for novel formulations of niclosamide.
