Keywords: ChatGPT, large language models (LLMs), academic writing, scientific terminology,
PubMed, AI-influenced terms, medical literature, language evolution.

Abstract

It is estimated that ChatGPT is already widely used in academic paper writing. This study aims to
investigate whether the usage of specific terminologies has increased, focusing on words and phrases
frequently reported as overused by ChatGPT. A list of 142 potentially AI-influenced terms was
curated from online discussions and recent literature documenting LLM vocabulary patterns, while
84 common academic terms in the medical field were used as controls. PubMed records from 2000 to
2024 were analyzed to track the frequency of these terms. Usage trends were normalized using a
modified Z-score transformation. A linear mixed-effects model was used to compare the usage of
potentially AI-influenced terms to common academic terms over time. Among the potentially AI-
influenced terms, 100 displayed a meaningful increase (modified Z-score ≥ 3.5) in usage in 2024.
The linear mixed-effects model showed a significant effect of potentially AI-influenced terms on
usage frequency compared to common academic phrases ($p < 0.001$). The usage of potentially AI-
influenced terms showed a noticeable increase starting in 2020. This study revealed that certain
words, such as "delve," "underscore," "meticulous," "boast," and "commendable," have been used
more frequently in medical and biological fields since the introduction of ChatGPT. The usage rate of
these words/phrases has been increasing for several years before the release of ChatGPT, suggesting
that ChatGPT might have accelerated the popularity of scientific expressions that were already
gaining traction. The identified terms in this study can provide valuable insights for both LLM users,
educators, and supervisors in these fields.

31 1   Introduction

32 ChatGPT rapidly achieved widespread global use after its launch on November 30, 2022. Trained on
33 a vast corpus of text data, the large language model (LLM) including ChatGPT generates natural
34 language with remarkable fluency. Shortly after its release, ChatGPT's applicability for scientific
35 writing in medical and biological fields became evident (Biswas, 2023; Salvagno et al., 2023). Due to

the fervor surrounding its capabilities, it was credited as an author on several papers, igniting considerable debate (currently, AI is not acknowledged as an author in scholarly publications (Lin, 2024b)). There were even opinions that the use of ChatGPT in paper writing was plagiarism (Thorp, 2023), but in reality, LLMs such as ChatGPT, Gemini, and Claude are already being used in paper writing. The use of LLMs can be applied in various ways in academic writing (Biswas, 2023; Alyasiri et al., 2024; Lin, 2024a) and is also important for the research activities of non-native researchers whose first language is not English (Berdejo-Espinola and Amano, 2023; Hwang et al., 2023; Matsui et al., 2023). Presently, a framework has been established that permits the use of LLMs in writing, provided their involvement is adequately acknowledged (Lin, 2024b).

While LLMs can produce natural writing, their output also exhibits certain characteristics (AlAfnan and MohdZuki, 2023; Liao et al., 2023). Recent reports focusing on detecting text generated by LLMs have identified several frequently used words, such as 'commendable,' 'meticulous,' 'intricate,' and 'realm' (Geng and Trotta, 2024; Gray, 2024; Liang et al., 2024a; Liang et al., 2024b). The extraction of these characteristic keywords of LLMs in these previous reports was performed by comparing human-generated text with ChatGPT-generated text (Geng and Trotta, 2024; Liang et al., 2024a; Liang et al., 2024b). While this approach revealed ChatGPT's characteristics among the words commonly used by both humans and ChatGPT, it had methodological limitations in extracting words with low usage frequencies. Clarifying the word expressions that LLMs tend to use in medical and biological papers is crucial for designing academic writing support and medical education programs (Song and Song, 2023). Moreover, revealing the extent of ChatGPT's impact on papers in the medical and biological fields is essential for maintaining the fairness and reliability of academic research and from the perspective of research ethics (Jeyaraman et al., 2023). However, the existing literature lacks a thorough investigation of the specific ways in which ChatGPT has transformed academic writing practices in the medical and biological disciplines, necessitating further research.

As the usefulness of LLMs becomes more evident, the number of researchers using LLMs for writing papers has been gradually increasing (Cheng et al., 2024; Geng and Trotta, 2024; Liang et al., 2024b). It would logically follow that there has been an increase in the number of research reports featuring specific expressions unique to LLMs. Despite anecdotal observations of LLMs favoring particular words like 'delve,' quantitative evidence regarding the increased usage of such specific, informally identified LLM-associated terms in scholarly publications remained scarce when this study was initiated. This study, therefore, tested the hypothesis that the adoption of certain scientific terminologies has risen following the advent of ChatGPT. Focusing on words and phrases frequently reported as overused by ChatGPT, I investigated PubMed records from 2000 onwards and performed a comparison using terms commonly used in medical research as a control. This analysis aims to empirically explore the influence of LLMs on the lexicon of medical literature.

2   Materials and methods

2.1   Search for records

To investigate the influence of LLMs on vocabulary usage in medical literature, I constructed a comprehensive list of potentially AI-influenced terms using a two-step approach. First, as an exploratory seed step, potentially AI-influenced terms were manually curated from publicly accessible online discussions (e.g., social media platforms, blogs, forums). Terms were included if independently identified by at least two different users as 'overused by ChatGPT or other LLMs,' across multiple online sources. Terms that appeared to be proper nouns, such as disease names, were

excluded. Second, to address the inherent biases of manual curation and to broaden coverage of potentially overlooked terms, I reviewed recent literature reporting vocabulary disproportionately employed by LLMs (Gray, 2024; Kobak et al., 2024; Liang et al., 2024a; Liang et al., 2024b; Yakura et al., 2024; Juzek and Ward, 2025). All terms meeting the original inclusion criteria from these sources were added to the initial exploratory set. The final list comprised 142 potentially AI-influenced terms (Table 1). For comparison, I created a control group of common academic words or short phrases (up to two words) in medical research by extracting items from the four-word lexical bundles identified in a previous study (Qi and Pan, 2020). After excluding expressions that contained words listed as potentially AI-influenced terms in this study, such as 'significant,' 'finding,' and 'potential,' a final set of 84 PubMed-searchable expressions was obtained (Table 1).

I used PubMed's advanced search feature (https://pubmed.ncbi.nlm.nih.gov/advanced/) to reveal the number of records in which these words were used by searching for "Text Word". To ensure comprehensive coverage of verb forms in English, the search query included the base form, third person singular present, present participle/progressive, past tense, and past participle. For nouns, both singular and plural forms were incorporated. Considering the daily increase in records indexed in PubMed, the search conditions were standardized from January 1, 2000, to December 31, 2024. The search formulas for all words/phrases are shown in S1 Table.

2.2 Statistical analysis

To investigate the usage trends of potentially AI-influenced terms in the PubMed database, I first calculated the usage frequency of each term by dividing the number of records containing the term by the total number of records in PubMed for each year from 2000 to 2024. This process yielded a dataset with usage frequency for each term and year.

Next, the modified Z-score transformation was used to normalize the usage frequency and facilitate comparisons across terms and years. For each term, the median and median absolute deviation (MAD) were calculated. The modified Z-score was computed by subtracting the median from each occurrence rate, dividing the result by the MAD, and multiplying by 0.6745. An absolute modified Z-score of 3.5 or higher was considered indicative of a meaningful increase or decrease in term usage to identify significant deviations (Crosby, 1994). Then, a linear mixed-effects model was used to compare the usage of potentially AI-influenced terms and common academic phrases from 2000 to 2024. The data, consisting of modified Z-scores for each word or phrase, were obtained and reshaped into a long format. The model, constructed using the 'lme' function from the 'nlme' package in R, included the modified Z-scores as the dependent variable, the group (potentially AI-influenced terms or common academic phrases) as a fixed effect, and a random intercept for each word or phrase to account for repeated measures. The model's summary was generated to assess the significance of the fixed effect of the group on term usage. A line plot with 95% confidence intervals was created using the 'ggplot2' package to visualize the trends in mean usage for each group from 2000 to 2024. The significance level for all statistical tests was set at 0.05. These analyses were performed using R version 4.3.2.

3 Results

The analysis covered a total of 27,501,542 records indexed in PubMed between January 1, 2000, and December 31, 2024. The frequency rates of each word/phrase were determined using the annual total number of records as the denominator, followed by the calculation of the modified Z-score.

In this study, among the 142 potentially AI-influenced terms verified, 100 words/phrases exhibited a
modified Z-score exceeding 3.5 in 2024. The increase was particularly pronounced for many terms at
the top of this list, with 'delve,' for instance, showing an exceptionally high Z-score. Other
significantly increased terms included 'underscore,' 'meticulous,' 'boast,' 'commendable,' 'showcase,'
'surpass,' 'intricate,' 'tapestry,' and 'emphasize' (see S2 Table for the full list and Figure 1 for visual
trends). While the majority of the 84 common academic phrases (controls) displayed no remarkable
deviations in usage rates, 'further research' and 'aim to' also surpassed a modified Z-score of 3.5 in
2024. On the other hand, phrases such as 'purpose of,' 'end of,' 'to determine,' 'hypothesis,' 'results
suggest,' 'all patients,' and 'treatment of' showed a notable decrease (modified Z-score < -3.5) in the
same year (details in S2 Table).

The linear mixed-effects model revealed a significant effect of the group (potentially AI-influenced
terms vs. common academic phrases) on the modified Z-scores of term usage. The model showed
that the usage of potentially AI-influenced terms was significantly higher than that of common
academic phrases ($\beta = 0.587$, SE = 0.079, t(224) = 7.446, p < 0.001). The line plot (Figure 2)
illustrates the trends in mean frequency for potentially AI-influenced terms and common academic
phrases from 2000 to 2024. While the frequency of the control group remains relatively stable, the
potentially AI-influenced terms, following a period of gradual increase, exhibit a notable and steep
upward trajectory starting in 2020, which becomes particularly pronounced in 2023 and 2024.

4   Discussion

The present investigation showed that, in the fields of medicine and biology, a number of specific
words and phrases, led by 'delve,' 'underscore,' 'meticulous,' 'boast,' and 'commendable,' have come to
be used more frequently following the advent of ChatGPT. The increasing trend in the usage rates of
these words/phrases was more pronounced in 2024 than in 2023 in almost all cases. This may reflect
the generalization of LLM use among researchers in the fields of medicine and biology, as shown in
previous findings (Liang et al., 2024b). The list of overused terms suggested in this study will help
those writing with LLMs centered around ChatGPT.

It has been observed that medical texts generated by ChatGPT, while fluent and logical, tend to
include less specific information and more generalized expressions compared to those authored by
humans, which feature a richer and more diverse content (Liao et al., 2023). In general papers, it has
been noted that ChatGPT tends to 1) use the same style and expressions repeatedly, 2) show a
decrease in the frequency of basic verbs like 'is' and 'are,' and 3) frequently use adjectives and
adverbs (Geng and Trotta, 2024). Particularly for adjectives and adverbs, numerous words that
ChatGPT frequently uses have been pointed out (Liang et al., 2024a). Because this study only
counted the records where specific words or phrases occurred, it did not evaluate the weight of terms
appearing multiple times. In the current study, several words that were previously identified as
frequently used by ChatGPT did not exhibit a notable increase in usage; yet, ChatGPT may actually
overuse these words more than suggested by the results of this study. Similarly, frequently used verbs
such as 'significant,' 'enhance,' 'essential', and 'particularly' may also have been overused by LLMs
more than suggested by this study.

A limitation of previous reports lies in their lack of focus on identifying specific terms whose usage
has notably increased in academic writing following the widespread adoption of LLMs like
ChatGPT, thus failing to comprehensively explore these characteristic terms. Specifically, the

increased usage of the word 'delve' was incredibly pronounced compared to other words or phrases,
with a modified Z-score above 100. Despite its overwhelming presence, earlier comparative analyses
of human- and ChatGPT-generated texts (Gray, 2024; Liang et al., 2024a; Liang et al., 2024b) did
not mention 'delve,' instead focusing on broader stylistic shifts. It is only in more recent, fine-grained
corpus investigations that 'delve' has been flagged as a conspicuously overrepresented term in AI-
assisted biomedical writing (Kobak et al., 2024; Masukume, 2024; Yakura et al., 2024; Juzek and
Ward, 2025); this study was among the first to identify and highlight that trend. While this study
cannot conclusively establish a direct causal link between the increased use of "delve" and the
emergence of ChatGPT, its influence is strongly suspected. Multiple potential factors—including
training corpus composition, model architecture, tokenization methods, and context priming—could
explain why ChatGPT frequently selects 'delve.' However, recent discussions suggested that
reinforcement learning from human feedback (RLHF) might have exerted the strongest influence
(Juzek and Ward, 2025). This indicated that human evaluation during model fine-tuning might have
unintentionally encouraged stylistic word preferences, leading language models to increasingly favor
particular terms such as 'delve.'

Interestingly, some of the common academic phrases used as controls also deviated in their
proportion of use in 2024. The two phrases 'further research' and 'aim to' markedly increased in
frequency of use in 2024, but since they are very commonly used expressions in medical academic
writing, it would be difficult for us humans to recognize that their frequency has increased.
Conversely, the seven phrases 'purpose of,' 'end of,' 'to determine,' 'hypothesis,' 'results suggest,' 'all
patients,' and 'treatment of' notably decreased in usage in 2024. When interpreting these results, we
must remember that the language used in papers naturally evolves over time (Park et al., 2023); for
example, 'hypothesis' and 'results suggest' decreased in frequency had already been declining even
before the introduction of ChatGPT. In addition, the usage rate of 'results suggest' showed
considerable variation from year to year. However, the phrase 'all patients' did not show a noticeable
decrease in frequency of use before 2022, and its frequency of use appears to have decreased
significantly after 2023 (see S2 Table). This suggests that AI tools, such as ChatGPT, might already
be subtly influencing the usage patterns of certain common academic phrases. While these phrases
were selected as controls due to their frequent use in medical writing, they may have already been
impacted by the emergence of AI-assisted writing.

Notably, the frequency of use for the potentially AI-influenced terms investigated in this study had
already diverged markedly even before ChatGPT's release in November 2022. The observed trends
suggest a complex interplay between evolving scientific writing styles and the development of
LLMs. These models, including ChatGPT, are trained on vast corpora of text data that inherently
include academic and scientific writings (Cheng et al., 2024; Geng and Trotta, 2024; Liang et al.,
2024b). The gradual increase in usage of certain terms prior to ChatGPT's release may have created a
recency bias in the training data, making these terms appear more relevant or current to the model.
This temporal bias could have been further amplified by the RLHF during model fine-tuning
(Ouyang et al., 2022; Juzek and Ward, 2025). Moreover, the increased use of specific terms in one
scientific domain may have led to their adoption in other fields, a trend that LLMs could have picked
up and subsequently amplified across disciplines. For instance, the word 'delve,' which showed a
significant increase in usage in this study, seemed traditionally commonly used in the fields of
computer science (Akujuobi and Zhang, 2017). Furthermore, early adopters of AI writing assistants
may have been exposed to and subsequently incorporated these terms into their writing, creating a
human-mediated pathway for these linguistic patterns to propagate. This complex feedback loop
between human writers, scientific literature, and AI language models can be more prominent in the
future, specifically without being apparent to human observers. While these hypotheses remain

speculative at this point, it seems highly likely that the emergence of LLMs has accelerated the naturally occurring linguistic trend changes in human scientific communication (Kobak et al., 2024; Yakura et al., 2024). The subtle nature of these changes underscores the importance of continued vigilance and research to understand the evolving dynamics between AI language models and academic writing styles.

It should be noted that this study does not intend to criticize LLM use; for many researchers, especially non-native English speakers, these tools are increasingly valuable (Berdejo-Espinola and Amano, 2023; Hwang et al., 2023; Matsui et al., 2023). Rather, by identifying specific linguistic patterns—some of which, as discussed, were trending even before widespread LLM adoption—I aim to develop critical awareness. This awareness can empower authors to use LLMs more thoughtfully, refining their manuscripts to improve clarity and preserve their unique authorial voice. Educators and supervisors can apply these insights to encourage best practices in LLM-assisted writing; this includes guiding researchers to be critically aware of potentially overused terms and to actively diversify their vocabulary. Furthermore, it involves emphasizing careful human editing to preserve the author's unique voice and ensure originality, and promoting the view of LLMs as supportive tools for drafting and idea generation rather than as final content creators.

This study is subject to several limitations. The most important limitation is that the potentially AI-influenced terms were initially identified through a process that included manual curation from publicly accessible online discussions. This approach is inherently susceptible to selection bias, as the researcher's judgment, potentially amplified by the single-author nature of this study, and the specific terms prominent in the surveyed online discussions at the time of data collection could have influenced which terms were included or excluded. Although this initial list was subsequently expanded by reviewing recent literature to mitigate bias and broaden coverage, it is still possible that some words or phrases showing a significant increase in usage after ChatGPT's emergence were not captured by this study. Additionally, temporal shifts in the frequency of word or phrase use could have been influenced by external factors such as evolving research trends and shifts in the style of scientific communication, factors not accounted for in this study. The introduction of new research topics, particularly in rapidly evolving fields such as artificial intelligence, biotechnology, and pandemic-related studies, may have also contributed to these changes in language use. Secondly, the modified Z-score was applied to the time series data. The threshold for identifying significant deviations (absolute value ≥ 3.5) was based on convention rather than strict theoretical grounds, potentially affecting the identification of significant changes. While I initially considered more complex time series models, the limited number of annual data points rendered them unsuitable, likely leading to model instability. This informed my decision to employ the modified Z-score, focusing on deviations from central tendency within each year. Thirdly, the study may have been influenced by the presence of certain proper nouns. For example, there is a service called "Microsoft Delve." A PubMed search for (("microsoft"[Text Word]) AND ("delve"[Text Word]) AND (("2000/01/01"[Date - Publication] : "2024/12/31"[Date - Publication]))) yielded only four hits, suggesting that the impact of "Microsoft Delve" on the results is likely minimal. However, there remains a possibility that other unforeseen proper nouns could have influenced the usage frequency of some terms.

5   Conclusion

This study demonstrated the increased prevalence of specific words and phrases in academic writing following the introduction of ChatGPT. The list of selected terms discussed in this study can be advantageous for both users employing LLMs for writing purposes and for individuals in educational and supervisory capacities within the fields of medicine and biology. As LLMs evolve, distinguishing between human and AI-generated text may become more challenging (Herbold et al., 2023). However, simultaneously, there is a possibility that qualitative shifts in academic terminology may evolve in subtle, imperceptible ways, eluding human detection; future research should adopt more sophisticated methods to track and understand these nuanced changes. Many researchers are expected to continue using LLMs for their writing—needless to say, adhering to ethical aspects and taking responsibility for the final output is crucial for the authors when using these tools.

Data availability statement

All data and code are available at https://github.com/matsuikentaro1/delving_into_pubmed_records.

Ethics statement

Written informed consent was not applicable for this study as it involved the analysis of publicly available bibliometric data from PubMed. No individual participant data beyond publicly accessible author information was collected or analyzed, and the study did not include any potentially identifiable images or private data of individuals.

Funding

This work was supported by the Japan Society for the Promotion of Science (JSPS) KAKENHI (grant number 22K15778).

Acknowledgments

During the preparation of this work, the author used ChatGPT (GPT-4 and GPT-4o, by OpenAI), Claude (Claude 3 Opus, Claude 3.5 Sonnet, and Claude 3.7 Sonnet, by Anthropic), and Gemini (Gemini 1.5 Pro, by Google) for specific technical assistance: drafting initial R code templates for statistical analysis, improving sentence structure for clarity, and general proofreading. These AI tools were used as writing and programming aids only, with all scientific conceptualization, interpretation of results, and conclusions being exclusively the author's work. After using these services, the author reviewed and edited the content as needed and takes full responsibility for the content of the publication.

Table 1. Words and phrases examined for usage rates

Potentially AI-influenced terms
Verbs
align, boast, bolster, burgeon, captivate, catalyze, compel, comprehend, delve, demystify, dive, elevate, elucidate, embark, embrace, employ, emphasize, encompass, encounter, endeavor, enhance, enrich, excel, explore, facilitate, fortify, foster, garner, grapple, harness, highlight, juxtapose, leverage, mitigate, navigate, nuance, offer, optimize, pave, pioneer, resonate, reveal, revolutionize, safeguard, shed light, showcase, streamline, stem, surpass, underscore, unearth, unleash, unlock, unravel, unveil, utilize

Adjectives
adept, aesthetic, commendable, comprehensive, crucial, cutting-edge, disruptive, dynamic, essential, ever-evolving, fresh, groundbreaking, holistic, illustrious, imperative, innovative, invaluable, intricate, keen, meticulous, methodical, multifaceted, noteworthy, overarching, paramount, pivotal, poised, potent, potential, renowned, robust, seamless, significant, tailored, transformative, unparalleled, unprecedented, unwavering, valuable, versatile, vibrant, vital

Adverbs
additionally, aptly, effectively, excellently, impressively, ingeniously, moreover, notably, particularly, reportedly, scholarly, strategically, ultimately, undoubtedly

Nouns
advancement, adventure, beacon, capability, complexity, cornerstone, digital world, driving force, enigma, finding, game-changer, hurdle, insight, interplay, intersection, intricacy, journey, kaleidoscope, landscape, new era, paradigm shift, prowess, realm, spearhead, state-of-the-art, symphony, synergy, tapestry, testament, treasure trove

Common academic words or phrases in the medical field (control)
adverse events, aim of, aimed to, all patients, analysis, associated with, association between, at least, basis of, cohort study, common grade, compared with, control group, cross-sectional, difference between, difference in, dose of, effect of, efficacy, end of, end point, evaluate, examine, further research, higher in, hypothesis, identify, included in, increased risk, independently associated, investigate, is known, less likely, logistic regression, lower in, median follow-up, models, more likely, most common, no difference, objective of, one of, our results, outcome measure, patients who, placebo group, primary endpoint, primary outcome, proportion of, purpose of, randomly, ratio, registered with, regression analysis, results suggest, retrospective, safety, secondary analysis, sought to, statistically, study period, suggest that, this study, this trial, time of, to assess, to compare, to determine, to evaluate, to examine, to identify, to investigate, to receive, treatment allocation, treatment assignment, treatment of, two groups, was found, was used, were assessed, were collected, were enrolled, were performed, were reported

Figure legends

Figure 1. Scatter plot of word/phrase usage frequency vs. modified Z-Score in 2024.
Figure 1 illustrates the relationship between the frequency of use and the modified Z-scores for
words and phrases with absolute modified Z-scores exceeding 3.5 in 2024. Red circles represent
potentially AI-influenced terms, while grey circles represent common academic terms in the medical
field (control). The x-axis shows the number of total records using the words/phrases on a
logarithmic scale, and the y-axis displays the modified Z-score for usage frequency, also on a
logarithmic scale.

Figure 2. Mean usage (modified Z-scores) of potentially AI-influenced terms and common academic
phrases from 2000 to 2024. Shaded areas represent 95% confidence intervals.
