Abstract

Objective: Complement biomarker analysis in ocular fluid samples from subjects with geographic atrophy (GA) in a Phase I/II clinical trial of subretinal AAV2 complement factor I (*CFI*; FI) gene therapy, PPY988 (formerly GT005), to understand target pharmacokinetics/pharmacodynamics. Clinical findings were subsequently utilized to investigate the therapeutic dose in an *in vitro* complement activation assay.

Design, setting and participants: Biomarker data were evaluated from 28 subjects in FOCUS, a Phase I/II clinical trial evaluating the safety and efficacy of three ascending doses of PPY988.

Main outcomes and measures: Vitreous humor (VH), and aqueous humor (AH) from subjects before surgery and at serial timepoints (week 5 or 12, 36, 96) were evaluated for changes in levels of intact complement factors I, B and H (FI, FB, FH) components C3, C4, and C1q and breakdown products (Ba, C3a, C3b/iC3b, C4b) using validated assays and OLINK® proteomics.

A modified *in vitro* assay of complement activation modelling VH complement concentrations was used to compare PPY988 potency to the approved intravitreal C3 inhibitor pegcetacoplan (Apellis) and complement Factor H (FH).

Results: An average 2-fold increase in VH FI was observed post-treatment at week 36 and week 96. This correlated with a marked post-treatment reduction in VH concentration of the FB breakdown product Ba and Ba:FB ratio, but minimal changes in C3a and C3b/iC3b levels. Variable concordance in complement biomarker levels in VH versus AH suggest AH is not a reliable proxy for VH for complement activation. During the experimental comparison of doses, a 2-fold increase of FI achieved in the vitreous had only a minor effect on the complement amplification loop *in vitro*, indicating limited impact [IC50: 1229nM]. Pegcetacoplan completely blocks C3a generation at concentrations much lower than the estimated trough level for monthly intravitreal injections [IC50: 2nM]. Supplementation with FH in the assay revealed similar potency to pegcetacoplan [IC50: 6nM].

Conclusions and relevance: PPY988 subretinal gene therapy may not have provided sufficient FI protein to meaningfully modulate complement activation to slow GA growth. Reviewing VH biomarkers is important for understanding target expression, pathway engagement, and determining optimal dose, thereby informing future clinical development.

Introduction

Age-related macular degeneration (AMD) is a leading cause of blindness,

particularly in developed countries. In the United States (US) alone, there are

approximately 18 million individuals aged 40 and above with early-stage AMD, and 1.5

million with late-stage AMD, which includes geographic atrophy (GA) and/or

neovascular AMD [1]. GA is a condition characterized by the progressive loss of

photoreceptors, retinal pigment epithelium (RPE), and underlying choriocapillaris,

resulting in a central scotoma [2]. Reduced vision can significantly impact activities of

daily living and quality of life [3,4]. There have been two recent Food and Drug

Administration (FDA)-approved therapies that inhibit complement activity, with a

modest slowing of GA growth [5,6]. However, they require life-long monthly or bimonthly

intravitreal (IVT) injections and have so far exhibited limited functional efficacy that

present challenges for long term compliance [7]. Therefore, a one-time gene therapy

that provides long-lasting efficacy equivalent to or better than repeated IVT therapies

is a promising avenue for exploration.

One such gene therapy, called PPY998 (formerly GT005), is a subretinal gene

therapy that supplements complement factor I (*CFI*; FI) protein in the retinal layers

where atrophy occurs [8]. A Phase II study (HORIZON, NCT04566445) was initiated,

however a decision to stop the PPY988 program was taken by Novartis based on

a recommendation from the independent Data Monitoring Committee following an

overall benefit-risk assessment of available data from the program studies. [Press

release: Novartis AG; September 11th 2023, : https://www.novartis.com/news/gt005-

ppy988-development-program-geographic-atrophy]. This raises important questions

about whether *CFI* was sufficiently expressed after subretinal gene therapy, whether

there was evidence of modulation of intraocular complement activity, or if this

modulation was sufficient to potentially alter the disease course. Such information is

crucial to the retina community, as there are many companies developing complement

modulating therapies for AMD [9]. Sharing the learnings from the PPY998 program

would improve the risk-benefit analysis for these programs and help understand if new

approaches differentiate from PPY998, justifying further clinical study of complement

targets for GA.

The complement system, specifically the alternative pathway (AP), plays an

important role in the development of AMD, and increasing local FI concentration could

be a promising approach to regulate ocular complement activity. The AP is a part of
the complement system that constantly surveys for foreign cells and debris and
requires tight regulation to prevent inflammation and self-cell damage [10]. Regulatory
proteins like factor H (FH), decay-accelerating factor (DAF; CD55), membrane
cofactor protein (MCP; CD46), complement receptor 1 (CR1; CD35), and FI help
control the AP, with FI being the only regulatory enzyme [11]. FI, expressed from the *CFI*
gene, cleaves C3b by forming a trimolecular complex with cofactors FH for C3b, and
MCP and CR1 for C3b and C4b [12–18]. Studies have shown that carriers of rare variants
(RV) in *CFI* have increased risk of developing advanced AMD and more rapid disease
progression [19–23]. *CFI* RV can result in low levels of serum FI (Type I variants) or
normal levels with functional impairment (Type II variants) [24,25]. Research has also
suggested that doubling serum FI levels may help control complement overactivation
driven by other AMD risk genetic factors mapping to complement genes [26]. Based on
these findings, clinical trials were conducted to explore the potential of sub-retinal
delivery of AAV2-*CFI* as a gene therapy for treating dry AMD [8].

The FOCUS study is a Phase I/II open-label study evaluating the safety, and
dose response of three doses of PPY988 AAV2-*CFI* subretinal gene therapy in GA. To
assess transgene pharmacokinetics and pharmacodynamics, vitreous humor (VH)
and aqueous humor (AH) samples were collected at baseline (BL) and four time points
up to 96 weeks after dosing and were evaluated for exploratory complement
biomarkers. This report shares findings regarding change from baseline in FI and
complement protein levels and activation, over time after vitrectomy and PPY988
administration. Levels of FI achieved in VH from FOCUS subjects were then used in
an *in vitro* simulated human vitreous complement activation assay, to gain insights on
the therapeutic potencies of FI, C3 inhibitor pegcetacoplan (Syfovre, Apellis), and FH.
We also offer critical learnings for other AMD complement gene therapy programs and
a guide for future analyses of complement biomarker data in ocular samples.

Ethics

The FOCUS study was conducted in accordance with the tenets of the
Declaration of Helsinki and all other local regulations, in accordance with the
International Conference on Harmonization E6 Guidelines for Good Clinical Practice
and with applicable local, state, and federal laws. Institutional review board or ethics
committee approval was obtained, and the study was registered at ClinicalTrials.gov
(reference: NCT03846193) and EudraCT (reference: 2017-003712-39). All subjects
provided written informed consent to participate, and an independent data monitoring
committee provided ongoing oversight.

Study design

FOCUS is an open-label first in human Phase I/II multicentre clinical trial to
evaluate the safety, and dose response of PPY988 (AAV2-*CFI)* [8], administered as a
single subretinal injection in subjects with GA secondary to AMD, followed for up to
240 weeks (5 years) post-dosing. Subjects were administered one of three doses to
the study eye under local anaesthesia by a qualified vitreoretinal surgeon: 2E10 viral
genome (vg; low), 5eE10 vg (medium) and 2E11 vg (high). At screening, a saliva
sample was taken from subjects and extracted DNA was analysed for *CFI* RV using
targeted next generation sequencing [21]. Genotyping results were not required at
screening if already available through participation in a previous Gyroscope sponsored
study. The term 'rare' was defined as variants that changed the *CFI* coding sequence,
had ≤1% minor allele frequency in GnomAD non-Finnish Europeans (V2.1.1,
accessed http://gnomad.broadinstitute.org), and were previously associated with FI
haploinsufficiency [11]. A detailed description of study design, route of administration,
dose, number of subjects, biomarker matrices, sampling timing and methodology are
provided in **Supplementary Methods and Supplementary Table 1.**

Complement protein and total protein quantification

AH and VH samples of subjects were taken on the treated eye immediately
prior to subretinal surgery at baseline (BL) and at 5 or 12 weeks, 36, and 96 weeks
post-treatment, as described in detail in **Supplementary Table 1**. Samples were
rapidly frozen at -80 °C and transported frozen for analysis. Prior to analysis, samples

were thawed and subjected to centrifugation at 17,000g for 10 minutes at 4°C.Samples
were kept on ice during sample preparation.

Complement factors C2, C4b, C5, C5a, factor D, mannose binding lectin (MBL),
FI, C1q, C3b/iC3b, C3, FH, FB and C4 were quantified in AH and VH using the
MILLIPLEX Human Complement Panel 1 and 2 (cat. no. HCMP1MAG-19K and
HCMP2MAG-19K, EMD Millipore Corporation, Billerica, MA) following extensive
quality control and validation of calibration curves. Plates were read using the Luminex
MagPix and xPONENT software (Luminex Corporation, Austin, TX). C5a was omitted
from further analysis as measurements fell under the lower limit for quantification.

Complement factors C3a and Ba were quantified in AH and VH using MicroVue
EIA kits (cat. no. A032 and A034, QuidelOrtho Corporation, San Diego, CA) following
manufacturer instructions. Plates were read using a Tecan Sunrise absorbance
microplate reader using the Magellan Tracker data analysis software (Tecan Trading
AG, Switzerland).

Each assay was validated and considered fit for purpose. Sample processing
and analyses were conducted in accordance with Good Clinical Laboratory Practice,
the analytes or measurements that did not meet acceptance criteria (coefficient of
variation of 20%, or 30% when results are below the lower limit of quantification but
above limit of detection) were excluded from the final analysis. The number of
successfully sampled subjects for each biomarker at each time-point is reported in
Supplementary Table 2.

Total protein was quantified in AH and VH using the Quant-iT protein assay kit
(cat. no. Q33210, Invitrogen, Thermo Fisher Scientific, Waltham, MA) as per the
manufacturer's instructions. Plates were read using a Varioskan LUX fluorescent
microplate reader using the SkanIt data acquisition software (Thermo Fisher Scientific,
Waltham, MA).

***In vitro* modelling the ocular complement system and potency assay**

The assay was performed using reagents from the Wieslab AP assay kit (cat.
no. COMPLAP330, Svar Life Science AB, Sweden) and purified human serum
complement proteins (Complement Technology Inc., Texas USA. All preparation steps
were performed on ice. Serial dilutions of the test analytes FI, FH and pegcetacoplan
were separately prepared and added to a mix of the complement components C3, FB,
FH, FI and Properdin simulating the final concentrations measured in the VH baseline

of FOCUS subjects (*CFI* RV negative population). The simulated vitreous complement
mix was transferred on the lipopolysaccharide (LPS) coated Wieslab plate on ice. FD
was separately added to the mix, the plate was immediately put at 37°C and incubated
for 1 hour. At the end of the incubation, the solution was transferred into a dilution plate
and kept on ice, EDTA was added to each well to obtain a final 20mM concentration.
Ba and C3a generated in the assay were measured by using the MicroVUE EIA kits
(cat. no. A032 and A034, QuidelOrtho Corporation, San Diego, CA) following the
manufacturer instructions. The ELISA plates were scanned using the Varioskan plate
reader and analysed using the SkanIT software (Thermo Fisher Scientific, Waltham,
MA). The *in vitro* FI potency comparability assay is described in **Supplementary**
Methods. The trough level of pegcetacoplan in the VH after 27 days was calculated
by halving the treatment dose of 15mg/eye 6 times (pegcetacoplan half-life 4.5 days),
the number obtained was converted to μg/mL using an estimated volume of VH of 4
mL [27].

Statistics

All subject sample biomarker analyses were performed in R version 4.1.0. The
analysis set consisted of all subjects who received subretinal delivery of PPY998 from
cohorts 1 to 4 and had at least one non-missing biomarker assessment performed at
BL and either week 36 or week 96. Given sparsity of data at week 5 and week 12, the
data were combined, and the average value was used in instances where subjects
had non-missing data from both visits. Concentrations values above the upper limit of
quantification (ULOQ) was set to ULOQ and values below the lower limit of detection
(LOD) were set to LOD. Please see Supplementary Tables 3-4 for limits.

Significance testing for the change in protein level from BL to week 36 or week
96 were performed on the differences of log-transformed data with the non-parametric
Wilcoxon rank-sum test. Means and standard error bars are shown in the respective
figures. Correlations between VH and AH sampling, as well as between FI and other
proteins, were summarized with the Spearman's Rank correlation coefficient. As
analyses were exploratory in nature and hypothesis-generating, no adjustments for
multiple testing were performed.

For the *in vitro* VH modelling assay, to calculate IC50s, 4-parameter logistic
curves were generated using GraphPad Prism version 10.0.0 for Windows, GraphPad
Software, Boston, Massachusetts USA, www.graphpad.com.

Results

Biomarker detection in FOCUS subjects that received PPY988

In FOCUS Part 1 and 2 (cohorts 1 to 4), 31 subjects received one of three doses
of PPY988 via the standard subretinal delivery approach (**Supplementary Table 1**). A
total of 97% of the ocular samples expected under the protocol were obtained prior to
early termination of the study which triggered cessation of further ocular fluid sampling.
A total of 88 VH, 63 AH and 45 plasma samples from 30 subjects were obtained at
various timepoints including BL, and 5 or 12, 36 and 96 weeks post-treatment
(**Supplementary Methods and Supplementary Tables 1 and 2**).
In FOCUS, PPY988 was well tolerated with no serious ocular AEs, some dose-
related RPE changes in the bleb area were evident and there was no clinically
significant vector-related inflammation. A full account of the FOCUS study safety and
clinical data, as well as full Phase II PPY988 safety, efficacy and biomarker data will
be reported separately following study completion.

Vitrectomy for subretinal AAV-*CFI* gene therapy procedure results in sustained
loss of protein from the VH

To test impact of total vitrectomy performed during transvitreal subretinal
delivery of PPY988 (**Figure** 1A and B) influencing global proteomic matrix changes
and biomarker analyses/interpretation, total protein (TP) measurements were
obtained at BL and each sampling timepoint (according to sample availability). In VH,
a ~30% reduction in TP from baseline was observed at either week 5 or 12 and week
36 (NS, P=0.162), with a significant >50% reduction identified at week 96 (P=0.033),
while there were minimal changes in AH TP at week 5/12, 36 or 96 (**Figure** 1C).
Because VH TP was reduced post-operatively, we performed TP normalisation to
compare the results with non-normalised data interpretation for VH but not AH.

AAV2-*CFI* delivery results in a sustained increase in FI protein level in the VH
and AH

Transgene expression was measured in VH and AH samples at weeks 5 or 12,
36, and 96 after treatment with PPY988. On average, we identified a 2-fold increase
in VH FI at week 36 compared to baseline, with non-TP normalized baseline
concentrations of 500 ng/mL compared to 1000 ng/mL at week 36 (non-normalised

P<0.001; TP normalised increase ~2-fold (P=0.002)) (**Figure** 2A, 2B). The increase in

FI concentration was sustained, with a ~2.5-fold increase in FI observed at week 96.

(mean ~1250 ng/mL) (non-normalised P<0.001; TP normalised increase ~3-fold

(P=0.002)). *CFI* RV (n=5) and non-*CFI* RV ('broad') (n=19) genotype groups

demonstrate comparable magnitudes of absolute FI elevation post-treatment, with the

overall *CFI* RV cohort FI starting concentration ~50% reduced (NS). Elevated FI

expression in AH samples at week 36 (P<0.001) were sustained out to week 96

(P<0.001) (**Figure** 2C, 2D). Lastly, there was a variable response to the three PPY988

doses in both VH and AH with no significant dose effect observed (Figure 2C, 2D).

.

Increased FI expression results in a reduction in Ba and Ba:FB in the VH

To test for FI target engagement at the level of formation of the alternative

pathway C3 convertase, we measured Ba and FB concentrations at each sampling

week after subretinal delivery of PPY988. A reduction in Ba in the VH is indicative of a

reduction in C3 convertase formation in the ocular environment. We observed that Ba

levels were reduced by ~2-fold compared to baseline at week 36 and 2.5-fold at week

96 in non-normalised data (week 36: P=0.004; week 96: P=0.003) (**Figure** 3A) and TP

normalised data (week 36: P=0.002; week 96: P=0.038) (**Figure** 3B). To add

confidence to this read-out by accounting for fluctuations in endogenous FB

biosynthesis, ratios of intact complement proteins and their breakdown products were

assessed as in previous studies [28–30]. Ba:FB ratio changes post-treatment reflected

the raw data. When reviewing biomarker levels from both non-normalized and TP

normalized datasets, a significant reduction in Ba:FB was observed at week 36 (both

P<0.001) and at week 96 (non-TP normalized (P=0.001); TP normalized (P=0.033))

(**Figure** 3C, 3D).

Increased FI expression results in modest alterations in VH and AH complement

biomarker profiles

To investigate the effect of PPY988 delivery on complement AP and classical

pathway (CP) activity, a panel of biomarkers including FI, C3, FB, FH, C1q, Ba, C3a,

C3b/iC3b, C4 and C4b were measured in the VH and AH (in addition to plasma) at BL,

week 5 or 12, week 36 and week 96. The complete set of concentrations at BL are

reported in the **Supplementary Table 3** (VH), **Supplementary Table 4** (AH), and

Supplementary Table 5 (plasma). In addition, Ba:FB, C3a:C3 and C3b/iC3b:C3 ratios

were calculated at each time-point. Baseline values for each biomarker with

descriptive statistics are reported in **Supplementary Table 3** (VH) and

Supplementary Table 4 (AH), with baseline and post-treatment pairwise correlations

between FI and biomarkers presented in **Supplementary Figure 1** (VH) and

Supplementary Figure 2 (AH). Fold changes in complement biomarker concentration

from baseline are presented for each biomarker or ratio at each post-surgery sampling

week in VH non-normalised data (**Figure** 4A), VH TP normalised data (**Figure** 4B) and

AH non-normalised data (**Figure** 4C). In the non-normalised VH dataset, we observed

reductions in Ba and Ba:FB, with a reduction in C1q possibly indicative of reduced

ocular immune cell (e.g. microglial) activation [31] **(Figure** 4A). We detected no

modulation of VH C3a and C4b. Although levels of C3b/iC3b per unit of C3 fall

substantially at week 96 in both non-normalized (P=0.002) and TP-normalized

(P=0.012) analyses (**Supplementary Figure** 3), pairwise correlation analyses reveal

that no biomarkers or ratios were negatively correlated with increasing FI level at week

36 or 96 post-treatment (**Supplementary Figures** 1 and 2). Minimal reduction of CP

activity was indicated by C4b:C4 ratio analysis, however, this was not observed when

normalizing for TP (**Supplementary Figure** 4). VH FB and FH concentrations do not

fluctuate substantially from BL values after treatment with PPY988. Overall, TP

normalisation did not substantially alter the interpretation of VH biomarkers with

broadly similar trends observed **(Figure** 4B).

AH sampling is not reflective of VH complement activation profile

Complement biomarker profiling in AH demonstrated increasing concentrations

of a majority of biomarkers (**Figure** 4C), including for Ba, C1q, and C3a (at week 96)

which was discordant with VH sampling data. Whether these components (C1q) and

breakdown products (Ba, C3a) are generated locally, systemically, or diffusely from

the retina or VH is unclear. A similar trend to VH was observed when considering the

increase in AH C3 and associated fall in C3a:C3 and C3b/iC3b:C3 ratios at week 96

in particular. However, in the case of AH, the increase in C3 was also observed at

week 36, suggesting compartmentalization of response of the AH vs the VH. In line

with these data, pairwise correlations between VH and AH levels of Ba, C3a and

C3b/iC3b post-treatment are modest and variable (**Supplementary Figure** 5), with

only FI consistently well correlated between the two ocular compartments.

Proteomic analysis on VH using Olink provides supportive evidence for target
expression and modest modulation of the complement system
Olink proteomic analysis of the VH samples identified a 2-fold median increase
in week 36 FI levels relative to baseline (**Supplementary Methods**, **Supplementary**
Figure 6a). Further review of differentially expressed proteins revealed trends for
elevation of additional complement components including factor B, properdin and C2
(**Supplementary Figure 6b, Supplementary Table 6).**
384
VH modelling of complement activation reveals inferior potency of FI vs
pegcetacoplan
By modelling the components of the VH based on median measurements of
C3, FB, FH, FI (broad cohort measurements) and properdin (all measurements) at
baseline in the FOCUS study, we compared the potency of FI, FH and the C3 inhibitor
pegcetacoplan for their effectiveness in controlling the generation of C3a on an LPS-
coated plate in a simulated ocular environment context (**Figure** 5). In this assay, C3
is directly activated by O-antigens on LPS thus triggering activation to drive the AP
amplification loop. A wide range of FI, FH and pegcetacoplan concentrations were
titrated through an artificial VH matrix so that comparisons could be made to clinically
relevant levels of both FI and pegcetacoplan. Serum purified FI was revealed to be of
similar potency to FI expressed from Good Manufacturing Practice (GMP)
manufactured PPY988 (**Supplementary Figure** 7). The trough level of pegcetacoplan
at 27 days was estimated using injection dose and half-life information available on
the Syfovre^{TM} prescribing information datasheet. No diffusion data in human was
available so this was not counted in the trough calculation. The concentration obtained
was similar to that reported in the pegcetacoplan rabbit pharmacokinetics (PK) study
and PK/PD prediction study published by Apellis [32,33]. Pegcetacoplan vitreal trough
level was compared to the 1st and 3rd quartile increase (at week 36 vs BL) in FI
associated with PPY988 delivery. Pegcetacoplan exhibited greater potency than FI,
with complete inhibition of the AP amplification loop and C3a generation at predicted
trough level (~59 µg/mL), whilst FI was observed to have minimal effect at levels of
expression associated with PPY988 after 36 weeks. Overall curves generated by
logistic regression revealed an IC50 of 1229 nM for FI, whilst FH [IC50: 6 nM] was
similar in potency to pegcetacoplan [IC50: 2 nM]. The estimated vitreous trough level
of pegcetacoplan was approximately 100-fold greater than that required for complete

inhibition of the AP in this assay. On the other hand, FI was observed to have minimal
effect on AP activation at the levels of PPY988 measured in VH after 36 weeks of
treatment.
414

Discussion

Gene therapy has been suggested as a promising treatment approach for

slowing macular degeneration in GA secondary to AMD. This manuscript describes a

comprehensive examination of the pharmacokinetic / pharmacodynamic properties of

complement biomarkers in the context of the PPY988 GA subretinal gene therapy

program and provides technical considerations for analyzing biomarker data from

treated subjects. Despite the early termination of the clinical development program,

the PPY988 study achieved notable milestones in the field, including the

implementation of subretinal delivery of gene therapy for GA and the use of serial

vitreous sampling. Herein, we present for the first time an analysis of VH complement

biomarkers at baseline and after surgical delivery of a subretinal gene therapy.

Baseline levels were similar to a previous study of VH complement [34] with potentially

confounding loss of total protein also observed in our study, highlighting the need to

analyze data in the context of changing total protein levels post-vitrectomy. Our

observations reveal consistent elevation of VH FI levels over a 96-week period,

accompanied by reduced detection of the FB activation product Ba and ratios of

Ba:FB, consistent with sustained modulation of complement AP activity in the vitreous

humor compartment. These data confirm that AAV gene therapy has a consistent and

lasting effect. Furthermore, although unpowered due to low N, the effects of FI gene

therapy on complement breakdown product biomarker profiles (Ba (**Figure 2A**) and

C3b/iC3b (**Supplementary Figure 3A**) appear to be comparable in both *CFI* RV

positive and negative sub-populations, which is counter to the original hypothesis of a

more dramatic effect in a sub-population with lower baseline FI levels [19,20]. However,

due to small sample size this finding should be interpreted with caution. Although the

impact on C3 breakdown products was minimal at week 36, it became significant at

week 96. Elevation of FI and modulation of the broader complement system was also

observed in Olink proteomic profiling of VH samples (**Supplementary Figure** 6),

supporting the complement biomarker findings in the validated panel. Elevated levels

of FI were detected in both AH and VH. PPY988 efflux from the sub-retinal injection

may have transduced cells in the anterior chamber of the eye resulting in an increase

in AH FI concentration. However, the correlation of other complement biomarkers

between VH and AH was inconsistent, in particular, Ba and C1q exhibited disparate

post-treatment trends (**Figure** 4), indicating that AH alone may not be a reliable

biomarker matrix for assessing the activity of complement biomarkers at the target

tissues. This cautionary advice should be considered in context of previous reports,

suggesting AH could be a broadly reliable proxy for VH [35], albeit that only full length

complement proteins were studied therein. To ensure quality control, protein level

normalization was added to the analysis comparing biomarker levels before and after

vitrectomy. Interestingly, the overall conclusions remained consistent regardless of

protein adjustment, which strengthens confidence in the study's findings. After

determining the futility of the Phase II study (HORIZON, NCT04566445), an *in vitro*

assay using clinically relevant levels of complement proteins was conducted to

investigate a possible biomarker-related explanation. The results showed that

pegcetacoplan had higher potency than FI in reducing C3 convertase activity *in vitro*

suggesting that limited *in-vitro* potency of FI may have contributed to the lack of clinical

success at Phase II. Although the translatability of the VH modelling assay to GA

remains to be demonstrated, FI's lower potency suggests that further increasing FI

concentration on its own by gene therapy may not achieve clinically meaningful levels

of C3 inhibition. It should however be noted that intravitreal pegcetacoplan will be at

its highest concentration in the mid-vitreous whereas FI will most likely be at the

highest level in the subretinal space where it is being produced. Hence directly

comparing vitreous levels of each compound may underestimate the activity of FI

compared with pegcetacoplan at the level of the subretinal space.

The lack of efficacy in the PPY988 Phase II study does not detract from the

viability of complement activation as an effective target for intervention in GA, given

the therapeutic effect observed for complement inhibitors pegcetacoplan and

avacincaptad pegol (Izervay; Iveric Bio) [5,6], and this study's observation that

pegcetacoplan achieves a much greater potency than FI *in vitro*. FI had a

disproportionally larger effect upon Ba compared to C3a and C3b/iC3b, which may be

due to the lability of C3a, differences in diffusion capabilities of the molecules from the

retina, and possible contribution of C3 concentration from the choriocapillaris as well

as biosynthesis by local immune cells. In addition, we hypothesize FI's capacity to

regulate the production of Ba without causing significant changes in the levels of C3b

and C3a in the fluid phase could be contributed to by regulation of AP tickover,

resulting from binding and activation of FB on water-hydrolysed C3 (C3H2O.) followed

by release of Ba[10]. Similarly, the intravitreal administration of a neutralizing factor D

Fab, which was found to be ineffective in Phase III trials for GA, was also able to

reduce ocular Ba levels [28]. However, it did not have a significant impact on the

generation of VH C3 breakdown products. In this study, by week 96, there was an

observed rise in the levels of full-length C3 and a corresponding decrease in the ratios

of breakdown products to full length. While the specific implications of this change are

uncertain, it potentially suggests a reduction in C3 consumption, which aligns with the

known activity of FI, but this may be confounded with upregulated biosynthesis of C3

given its acute phase nature [36]. C3 breakdown products only partially diffuse due to

cell-surface adherence. Based on this understanding, we hypothesize that changes in

C3 breakdown products may only become detectable when a certain threshold of

modulation in tissue complement activity is reached. Overall, the data suggests that

fully functional FI is being secreted into the VH, but the regulatory effects on the level

of Ba may be representative of convertase formation in the VH and not the macula

retina/RPE nor the choroid. To validate this hypothesis, one approach would be to

conduct vitreal sampling using an effective drug targeting C3 for GA in a larger cohort.

Further investigations are needed to gain a better understanding of these possibilities.

The study has several limitations that should be considered when interpreting

the results. Firstly, the study did not include a control group, which means that the

observed changes in complement biomarkers may not be solely attributed to

transgene expression. Other factors, such as the impact of subretinal gene therapy

administration triggering local inflammation or the effects of total vitrectomy on the

protein environment, could also contribute to these changes. During the study, no

significant safety concerns or adverse events were reported aside from dose-

responsive incidents of RPE changes in the area of the subretinal injection. However,

increased levels of antibodies to the vector and transgene were observed following

treatment [37]. It is important to note that these antibody levels were transient and

resolved shortly after treatment, indicating that the observed antibody responses were

not persistent or associated with any significant clinical consequences. It is worth

noting that the subjects included in this early clinical trial had more advanced disease

compared to the typical clinical trial GA population which may impact the

generalizability of the findings to the broader GA population. Additionally, the study had

a relatively small sample size, which increases the risk of bias. Furthermore, the

biomarker conclusions drawn from the study subjects may not be representative of the

subjects treated in the subsequent Phase II study. Therefore, caution should be

exercised when generalizing the findings to larger populations. Despite convincing and

robust genetic links to AMD reported for Type I *CFI* variants [19–22], this study observed

no difference in biomarker response when comparing *CFI* RV carriers to the broad

population. Interestingly, emerging data have revealed more modest ORs for *CFI* RVs

in progression from early to late AMD [23] and macular thinning was observed in UK

Biobank eyes of carriers <60 years old [38]. Moreover, the long-term effects of

complement therapy on the progression of GA are still uncertain. Another limitation to

consider is the translatability of the *in vitro* VH modelling assay to the disease

processes occurring in GA, and the relevance of the assay to cell-surface complement

activation occurring in the area of GA. The LPS-coated surface used for the VH

modelling assay would most likely result in more acute complement activation than in

the GA retina. Finally, this is a relative potency assay and does not take into

consideration the biodistribution of different modalities and routes of administration.

Despite these limitations, the conclusions drawn from this study are compelling and

hold significant implications for other gene therapy programs. The introduction of the

innovative *in vitro* complement activation assay serves as a valuable benchmark for

gene therapy programs.

The superior potency of FH compared to FI highlights the importance of

conducting potency comparisons using *in vitro* assays that reflect physiologically

relevant levels of complement proteins to guide decision-making. This finding opens

promising avenues for further investigation, with potential for engineering of more

active RCA protein truncates and chimeras including CR1, MCP, DAF and FH, FHRs.

To advance gene therapy programs, future research should focus on building upon the

pharmacokinetic / pharmacodynamic findings. It is crucial to establish tissue

concentrations and estimates of the target required for complement modulation before

moving into clinical stages. Pre-clinical assays that can be effectively translated to GA

remain elusive. Overall, the role of complement in GA and the potential benefits of a

safe one-time gene therapy in reducing AMD progression suggest the need for further

clinical development of complement gene therapy.

Conflict of interest

The authors declare the following competing interests: Drs T Hallam, E Gardenal, A Jones, S Ellis, E Pekle, K Carney, and L Drage and Ms C Wenden, Ms H Beadsmoore and Mr T Haye are employees of Gyroscope Therapeutics Limited, a Novartis company. Drs Poor, McBlane, Kaiser, Lu, Kassem, Cho, Ferraro, Rangaswamy, Obeidat, Saint-Geniez, and Grosskreutz are employees of Novartis. T Hallam is an author on a pending patent for factor I trimolecular complex building/screening of complement changes.

Claire L Harris (In previous three years: consultant: Q32 Bio, Biocryst; Grant funding: Ra Pharmaceuticals). CLH was an employee of Gyroscope Therapeutics Limited, a Novartis Company.

Professor David H Steel (Consultant: Alcon, Gyroscope, BVI, DORC, Eyepoint, Complement therapeutics, Alimera; Grant funding: Bayer, Alcon, Roche, DORC, BVI, Boehringer, Gyroscope Therapeutics Ltd).

Professor Robert E MacLaren (Consultant: Biogen, AGTC, and Beacon Therapeutics; Grant funding: Biogen). REM is also a named inventor on the Biogen BIIB112 patent licensed by the University of Oxford.

Acknowledgements

The authors thank all the subjects who took part in the FOCUS study, and Gyroscope Therapeutics and Novartis colleagues past and present who made this possible.

The authors thank Michael Wittpoth, Les McGuire, Jayashree Sahni, and Maria Costa from Novartis for assistance in providing critical comments on the manuscript, and Shyamtanu Datta for assistance with the *in vitro* modelling.

Figure Legends

Figure 1. Surgical delivery of PPY988 AAV2-*CFI*. (A) PPY988 vector design. FI protein

is secreted by cells targeted by AAV2 serotype and containing the cDNA sequence for

wild-type *CFI* (NM_000204.4) driven by a CAG promoter [8]. (B) Subretinal delivery of

PPY988. (C) Vitrectomy during SR delivery of PPY988 results in loss of total protein

(TP) in the vitreous humor. TP concentration (y-axis, log2 µg/µL) was measured at

baseline and 5 or 12, 36, and 96 weeks post-surgery (y-axis). Mean +/- SE is shown

by blue bars and lines whilst all subjects are shown by black lines for both vitreous

(left) and aqueous (right) humor. A significant reduction in TP was observed at week

96 in vitreous humor (*P=0.033). Significance is defined as *P<0.05. BL = Baseline;

WK= week.

Figure 2. Temporal expression of factor I (FI) in vitreous humor (VH) and aqueous

humor (AH) after PPY988 delivery. (A,B) FI levels (y-axis, ng/mL) in VH were

significantly increased at week 36 and 96 post-surgery (x-axis) both when non-

normalised (A) (P=0.001 for both timepoints) and total protein -normalised (B)

(P=0.002 at both timepoints). Mean +/- SE is shown by bars for all (black lines) broad

(blue lines) and CFI RV (green lines) groups. (C,D) FI level (y-axis, ng/mL) for each

subject in the cohort is tracked by week (x-axis) and separated by dose (2E10 vg:

orange lines; 5E10 vg: green lines; 2E11 vg: blue lines) in VH (C) and AH (with

significant increase in AH FI at week 36 and 96 (both P<0.001)) (D), where mean +/-

SE shown by black bars. Significance is defined as *P<0.05; **P<0.01, ***P<0.001. N

numbers are shown above X-axis. BL = Baseline; WK= week.

Figure 3. Modulation of Ba and Ba:FB by PPY988 delivery. (A,B) Ba concentrations

(Y-axis, ng/mL) in vitreous humor (VH) samples by week post-surgery (X-axis). Mean

+/- SE is shown by bars for all (black lines) broad (blue lines) and CFI RV (green lines)

groups. Significant reductions in Ba were observed at week 36 for both non-

normalised (P=0.004) (A) and total protein (TP) normalised (P=002) (B) data and week

96 for non-normalised data (P=0.003) and TP normalised (P=038). (C,D) Ratios of

Ba:FB concentration (y-axis, ng/mL) were calculated for each subject at each sampling

post-surgery week (x-axis). Mean +/- SE is shown by bars for all (black lines) broad

(blue lines) and *CFI* RV (green lines) groups. Significant reductions were identified at

week 36 for both non-normalised ($P<0.001$) (C) and TP normalised ($P<0.001$) (D)

Ba:FB ratios, with a reduction at week 96 for non-normalized ($P=0.001$) and TP

normalized ($P=0.033$) ratios. Significance is defined as *$P<0.05$; **$P<0.01$,

***$P<0.001$. N numbers are shown above X-axis. BL = Baseline; WK= week.

Figure 4. Modulation of complement AP and CP biomarkers by PPY988 delivery. Fold-

changes (y-axis) in complement biomarker [FI, C3, FH, FB, C1q, Ba, C3a, C3b/iC3b,

C4b, Ba:FB, C3a:C3, C3b/iC3b:C3] concentrations from baseline at each post-surgery

week (VH: week 5/12, 36 and 96; AH: week 36 and 96; X-axis) are shown in VH with

no normalisation (A), VH with total protein normalisation (B), and AH with no

normalisation. Mean is shown by thick black lines, +/- SE is shown by bars. Individual

subject changes are shown by grey lines. Yellow boxes highlight disparate trends in

VH vs AH biomarkers.   BL = Baseline; WK= week.

Figure 5. *In vitro* modelling of vitreous humor complement activation inhibition by FI

vs pegcetacoplan and additional complement regulators. FI (orange), FH (purple), and

pegcetacoplan (blue) were titrated (x-axis, ng/mL) through artificial vitreous

complement matrix on LPS-coated Weislab™ plates and C3a generation was

measured by ELISA (y-axis, ng/mL). C3a is a marker of convertase activity in the

complement activation cascade, the potency of complement inhibitors or regulators is

reflected in lower amount of C3a generated in the assay when testing comparable

concentrations. Mean is shown with +/-SD represented by bars and 4-parameter fit

logistic regression curves are shown by lines. The 1st-3rd quartile of increased FI

expression from baseline after 36 weeks of PPY988 delivery is shown by orange area.

The calculated trough concentration of pegcetacoplan in eyes 27 days after IVT

injection is shown by the blue vertical line.

Supplementary Methods

Study design

FOCUS was conducted at 13 sites over two countries and was sponsored by
Gyroscope Therapeutics, a Novartis company. Key inclusion criteria included a clinical
diagnosis of GA secondary to AMD in the study eye as determined by a retinal
specialist, and a diagnosis of AMD in the contralateral eye (except if subject was
monocular). Study eye GA lesion(s) total size was $\geq 1.25mm^2$ and $\leq 17.5mm^2$ (cohort 1
to 6) or $\geq 1.25mm^2$ (cohort 7), and GA lesions resided completely within the fundus
autofluorescence (FAF) fundus image. Key exclusion criteria included presence of the
following in the study eye; CNV, non-proliferative diabetic retinopathy, glaucomatous
optic neuropathy, or cataract. Subjects were also excluded if they had an active
malignancy or a history of vitrectomy, sub-macular surgery, macular photocoagulation
or previously receiving a gene or cell therapy in the study eye.

As outlined in **Supplementary Table 1,** the study had four parts, part 1 (cohorts
1-3); dose escalation, Part 2 (cohort 4); dose expansion, Part 3 (cohorts 5-6); dose
escalation with the Orbit Sub-retinal Delivery System (SDS), and Part 4 (cohort 7);
dose-expansion with the Orbit SDS.

PPY988 gene therapy aimed to transduce RPE and PR cells, considered a key
site for AMD pathology and FI production. Parts 1 and 2 (cohorts 1-4) delivered
PPY988 via standard transvitreal subretinal injection (TVSI), previously used for
subretinal gene therapy delivery [1,2]. The surgeon then performed the TVSI procedure
involving a standard 3-port pars plana vitrectomy. The retina was partially detached
through a cannula using buffered salt solution for bleb formation, and a fixed volume
of 0.1mL containing the gene therapy dose was injected into the bleb, which was
expected to flatten after 24 hours.

Subjects in Parts 3 and 5 (cohorts 5-7) received PPY988 subretinally via
suprachoroidal cannulation using Orbit SDS, a 510(k) cleared device in the US
(K200325, 14-Jul-2020, US FDA), developed to improve the safety profile of subretinal
injections as compared with TVSI [3]. However, because VH samples were not collected
in Parts 3 to 5, analysis of biomarker data from subjects treated in these cohorts is not
discussed herein.

VH, AH and plasma samples were collected from cohort 1 to 4 subjects at BL
prior to surgery, at weeks 12, 36 and 96 after dosing, except for sample collection at

week 5 (not week 12) in cohorts 1 and 2, and AH (not VH) was collected for cohort 4

at Week 12.

Approximately 25 to 100μL of AH and VH samples were collected under

microscopic visualization. AH samples were collected using a 30G needle attached to

a 1mL syringe. The 30G needle was entered into the anterior chamber through the

temporal limbus using a clear corneal approach. VH samples were collected at BL

using a non-primed 23G vitrectomy probe connected to a 1mL syringe, and post-BL

using a 30G needle through the *pars plana*. Immediately following collection VH and

AH samples were transferred to a sterile collection vial and frozen at –80°C within 30

minutes.

All subjects were assessed for the occurrence of adverse events (AEs) at each

follow-up visit and underwent functional visual and retinal imaging/anatomical

assessments and biological sampling for safety and immunogenicity monitoring at

periodic timepoints up to week 48, considered the primary endpoint timepoint of the

study.

It was intended that subjects would be invited to consent to an additional long-

term follow-up assessment until week 240 (5 years). At the time of Phase II study

termination, FOCUS was fully enrolled. As a consequence of the early termination of

the Phase II study, all ocular sampling in FOCUS from that point onward was

terminated, and subjects who had not completed the study assessment window to

week 48 were transferred onto a safety monitoring regimen.

Olink proteomics

VH samples from 17 subjects were analyzed using the OLINK® Target 96

platform (OLINK® Proteomics, Uppsala, Sweden) to identify broader pathway changes

affected by subretinal delivery of PPY988. A single measurement was performed for

each sample. The following 4 panels were assessed by Olink: inflammation and

inflammation II, cardiometabolic and neurology. Protein levels were measured on a

relative scale and presented as the normalized protein expression (NPX), which is an

arbitrary unit on a log2 scale. . Principal component analysis was performed to detect

outlier samples. Olink provides a limit of detection (LOD) for each protein based on

the background noise generated in negative controls (buffer run as a normal sample).

Nonetheless, the Olink protein expression data reported NPX values even for

measurements below the LOD. Low abundance proteins were excluded from the
statistical analyses. To identify the proteins changing over time relative to BL, a linear
mixed effect model was used. The model included the following covariates: timepoint,
subject age and sex, sample total protein content and *CFI* RV status (subject ID as
random effect). All analyses were carried out using R version 4.2.3. Nominal p-values
were adjusted using false discovery rate.

***In vitro* FI potency comparability assay**

HEK293 adherent cells with the *CFI* and *CFH* genes knocked out by CRISPR-
Cas9 were transduced with PPY988 (AAV2-*CFI*) vector material produced under good
manufacturing practice (GMP) at 10 different MOIs. After a 24-hour incubation (37°C
at 5% CO_2) with the vector, the media was replaced and left for a further 48 hours.
Supernatants were collected and stored at -20°C. Supernatants were thawed,
centrifuged (5000xG for 15 mins) then mixed with a fixed volume of human purified
C3b and FH (A114 and A137, Comptech) and incubated for 10 minutes at 37°C. The
mixture was then reduced and labelled by incubating for 5 minutes at 90°C with a
mixture of DTT, SDS buffer and the LIF dye Chromeo P503 (30693, Sigma). A standard
curve of Purified FI (Comptech, Tyler, TX) was made starting at a final concentration
of 4000 ng/mL down to 11 ng/mL. This was diluted in non-transduced control sample
media to ensure the same background matrix for both transduction supernatants
samples and Purified FI standard curve samples. Proteins were separated by CE-SDS
using LIF detection and an adapted version of a published method [4]. The areas of the
peak corresponding 114 kDa alpha prime subunit (normalised to the 75 kDa beta
subunit) are collected for both the Reference (Comptech Purified FI) and the Test
sample (AAV2-*CFI* GMP). The depletion of the peak of interest is plotted using QuBAS
3.0 Statistical Software (Quantics Biostatistics) which performs a parallel line
comparison of the Test compared to the reference and produces a Relative Potency
value corresponding to this analysis. Outliers are statistically identified by a Grubbs
Test and removed automatically from the analysis prior to calculating the Relative
Potency.

S Figure 1. VH Complement Biomarker pairwise correlation analysis

Supplementary Figure 1. VH complement biomarker pairwise correlation analysis. Pairwise correlation analysis of FI with intact complement proteins and breakdown products and ratios in the vitreous at baseline, week 36 and week 96 from subjects in cohorts 1 to 4. FI concentrations are shown by the x-axis while biomarker concentrations and ratios are shown by the y-axis. Correlations at BL are determined using log2 ng/mL concentrations, correlations at weeks 36 and 96 are determined using log2 fold change from BL. BL = Baseline; WK = week; FC = Fold Change; R = Spearman Correlation Coefficient; p = p-value.

S Figure 2. AH Complement Biomarker pairwise correlation analysis

Supplementary Figure 2. AH complement biomarker pairwise correlation analysis. Pairwise correlation analysis of FI with intact complement proteins and breakdown products and ratios in the aqueous humor at baseline, week 36 and week 96 from subjects in cohorts 1 to 4. FI concentrations are shown by the X-axis while biomarker concentrations and ratios are shown by the y-axis. Correlations at BL are determined using log2 ng/mL concentrations, correlations at weeks 36 and 96 are determined using log2 fold change from BL. BL = Baseline; WK = week; FC = Fold Change; R = Spearman Correlation Coefficient; p = p-value.

S Figure 3 – C3b/iC3b modulation after PPY988 delivery

Supplementary Figure 3. Modulation of C3b/iC3b and C3b/iC3b:C3 by PPY988 delivery. (A,B) C3b/iC3b concentrations (y-axis, ng/mL) in VH samples by week post-surgery (x-axis) from subjects in cohorts 1 to 4. Mean +/- SE is shown by bars for all (black lines) broad (blue lines) and CFI RV (green lines) groups. Significant reductions in C3b/iC3b were observed at week 36 for both non-normalised (P=0.029) (A) but not total protein (TP) normalised (P=0.271) (B) data, and at week 96 for non-normalised (P=0.038) but not TP normalised (P=0.069) data. Notably these reductions are modest compared to for Ba modulation. (C,D) Ratios of C3b/iC3b:C3 concentration (Y-axis, ng/mL) were calculated for each subject at each sampling post-surgery week (X-axis). Mean +/- SE is shown by bars for all (black lines) broad (blue lines) and CFI RV (green lines) groups. No reductions were observed at week 36 for either non-normalised (P=0.173) (C) or TP normalised (P=0.588) (D) C3b/iC3b:C3 ratios. However, reductions were observed at week 96 for non-normalized (P=0.002) and TP normalized (P=0.012) C3b/iC3b:c3 ratios. Significance is defined as *P<0.05; **P<0.01, ***P<0.001. N numbers are shown above X-axis. BL = Baseline; WK= week.

S Figure 4. Classical pathway engagement after PPY988 delivery

Supplementary Figure 4. Classical pathway (CP) engagement post-treatment with PPY988. Fold-changes (y-axis) in CP complement biomarkers [C1q, C4, C4b and C4b:C4] concentrations from baseline at each post-surgery week (VH: week 5/12, 36 and 96; AH: week 36 and 96; X-axis) are shown in VH with no normalisation (A), VH with total protein normalisation (B), and AH with no normalisation. Mean is shown by thick black lines, +/- SE is shown by bars. Individual subject changes are shown by grey lines. BL = Baseline; WK= week.

S Figure 5. Complement Biomarker VH vs AH BL and OT

Supplementary Figure 5. Pairwise correlation analysis of vitreous versus aqueous humor complement biomarkers at baseline and post-treatment from subjects in cohorts 1 to 4. VH concentrations on x-axis and AH concentrations on y-axis of FI, Ba, C3a and C3b/iC3b at baseline, week 36 and week 96 post-surgery. Vitreous and aqueous concentrations of FI and C3a significantly correlate at all time points, Ba concentrations correlate only at baseline, while C3b/iC3b concentrations only correlate significantly at week 36 post-treatment. BL = Baseline; WK = week; R = Spearman Correlation Coefficient; *p* = *p-value*.

S Figure 6. Olink analyses

Supplementary Figure 6. Proteomic analysis of vitreous humor using Olink. **(A)** Change in FI levels (Olink OID30772) over time. Median FI values measured at baseline, week 12, and week 36 are linked. Sample numbers were baseline; n=17, week 12; n=14, week 36; n=17. (B) Volcano plot of differential protein expression (week 36 relative to baseline). Minimum protein fold-change was set at absolute 1.5. Data points with a nominal p-value of less than 0.05 were considered statistically significant (red dots indicate significantly upregulated proteins, blue dots indicate significantly downregulated proteins and orange dots represent no significant change on a log2 scale).

S Figure 7. Comparability of commercial FI to PPY988 FI potency

Supplementary Figure 7. Comparability of commercial FI to AAV2-*CFI* potency. C3b alpha' chain breakdown normalised to C3b intact beta chain (y-axis) produced by increasing concentrations of PPY988 (GMP#3) in orange compared to commercial FI (Complement Technology (CompTech), Inc) in green. The serum purified CompTech FI protein was diluted in non-transduced control sample so that both FI (reference sample) and PPY988 FI (test sample) were in the same background matrix to ensure comparability. No difference in potency was observed between PPY988 and CompTech FI Protein. Relative Potency of PPY988**: 1.151;** 95% CI range: 1.065-1.244; Precision: 1.168. See supplemental methods for further details.

S Table 1. Overview of FOCUS Part 1 and 2 study design, dose, number of subjects and biomarker matrices

Part (name)	Cohort	SR delivery method	PPY988 dose [vg/eye]	Subjects (n)	Biomarker matrix; sampling timepoints
1 (dose escalation)	1	Standard	low, 2E10	3	VH; BL, week 5, 36, 96 AH; BL, week 36, 96 Plasma: BL, week 5, 36, 96
	2		mid, 5E10	4	VH; BL, week 5, 36, 96 AH; BL, week 36, 96 Plasma: BL, week 12, 36, 96
	3		high, 2E11	4	VH, BL, week 12, 36, 96 AH; BL, week 36, 96 Plasma: BL, week 12, 36, 96

2 (dose expansion)	4	Standard	low, 2E10 (n=3);
			mid, 5E10 (n=6);
			high, 2E11 (n=11)
				20	VH, BL, week 12, 36, 96
					AH; BL, week 36, 96
					Plasma: BL, week 12, 36, 96

Supplementary Table 1. FOCUS study overview. FOCUS consisted of four parts of either PPY988 dose escalation or expansion, divided by seven cohorts varying according to route of gene therapy administration, dose (vg; viral genomes), and biomarker matrix. Only Parts 1 and 2 (cohorts 1 to 4) are described given subretinal gene therapy delivery permitted vitreous humour (VH) sampling. VH, aqueous humour (AH) and plasma biomarker samples were collected from subjects prior to surgery at baseline (BL), and subsequent timepoints up to week 96 post-treatment. Emerging data and analysis on cohorts 1 and 2 indicated week 5 sampling from the VH was too early to evaluate an impact post-vitrectomy, so the first post-treatment evaluation for cohorts 3 and 4 was moved to a later time-point in the study (week 12), when it was expected that the proteome would have stabilised, and the transduced cells achieved maximal expression.
