Abstract

Introduction: We propose the Explainable AI (XAI) model for Clinical Decision Support Systems (CDSSs).
It supports physician's Differential Diagnosis (DDx) with Evidence-based Medicine (EBM). It identifies
instances of the case data contributing to the predicted diseases. It provides the evidence of the medical
literature from which the case data are sourced.
Methods: Case data (training data) for our CDSS are obtained from medical literature.
The prediction model (the main model) uses Neural Network (NN) + Learning To Rank (LTR). Physicians'
DDx and machines' LTR are remarkably similar.
The XAI model (the surrogate model) uses k-Nearest Neighbors Surrogate model (k-NN Surrogate
model). The k-NN Surrogate model is a symphony of Example-based explanations, Local surrogate model,
and k-Nearest Neighbors (k-NN). Requirements of the XAI for CDSS and features of the XAI model are
remarkably adaptable. To improve the surrogate model's performance, it performs "Selecting its data
closest to the main model."
We evaluated the prediction and XAI performance of the models.
Results: With "Selecting," the surrogate model's prediction and XAI performances are higher than those
of the "standalone" surrogate model.
Conclusions: The k-NN Surrogate model is a useful XAI model for CDSS.
For CDSSs with similar aims and features, the k-NN Surrogate model is helpful and easy to implement.
The k-NN Surrogate model is an Evidence-based XAI for CDSSs.
Unlike current commercial Large Language Models (LLMs), Our CDSS shows evidence of the predicted
diseases to medical professionals.

Keywords

Introduction

Clinical Decision Support System

Clinical Decision Support Systems (CDSSs) aim to improve medical care quality. CDSSs support medical decisions with clinical knowledge, patient information, and other medical information. (1)

The summaries of this article's CDSS are as follows:

- Objectives

    - To support Differential Diagnosis (DDx) by physicians and general practitioners.

    - To prevent diagnostic errors for medical professionals.

    - To reduce diagnostic uncertainty

- Medical literature, metadata, and case data

    Medical literature (textbooks, original articles, case reports, etc.) is a source of metadata and case data.
    Metadata (bibliographic and disease-related information) is obtained from the medical literature by text-mining.
    Case data (symptoms and diseases) is obtained from the metadata by coding. It is used for training and test of the models.
    Symptoms include signs and symptoms, laboratory and imaging test results, etc. (defined as "symptoms" from now on).
    Diseases include confirmed diseases, differential diseases, and their scores.

- Prediction model

    A medical professional inputs the patient's symptoms.
    The CDSS outputs predicted diseases by Artificial Intelligence (AI).
    Predicted diseases are a ranking list of diseases. (2)

- XAI model

    The CDSS outputs evidence of the predicted diseases by Explainable AI (XAI).
    Evidence is the metadata of the case data contributing to the predicted diseases. (3), (4)

Our CDSS is open to medical professionals on the Internet. (5) (See: Fig 1, S Table 1)

S Table 1 Example of the predicted diseases

Fig 1 Screen image of our Clinical Decision Support System

Case citation: (6)

CDSSs with similar aims and features are available worldwide. (7), (8), (9), (10)

Clinical Decision Support System and Learning To Rank

The prediction model of our CDSS uses Neural Network (NN) + Learning To Rank (LTR).
Physicians' DDx and machines' LTR are remarkably similar. (2)

Explainable AI

Explainable AI (XAI) aims to help humans accept the AI's behaviors.
The key points are interpretability and explainability. (11)

XAI has a variety of methods. (12), (13), (See: S Table 2)

Clinical Decision Support System and Explainable AI

Poor interpretability and explainability of CDSS are significant problems in medical ethics. This problem
has severe and far-reaching consequences for personal and public health. (14)

The XAI for CDSS has a variety of requirements. (15), (See: S Table 3)

XAI research in medicine is focused on image diagnosis and less on differential diagnosis. (16)

Research on XAI with CDSS for a single disease was reported about "Type 1 diabetes + SHAPE." (17)
A little research on XAI with CDSS for multiple diseases was reported.
No research on XAI to support Evidence-Based Medicine (EBM) was reported.

This manuscript proposes the Evidence-based XAI model for CDSSs.
This model supports the physicians' DDx with evidence.

Design

Objective

The aims of this article's XAI model are as follows:

-     Requests from medical professionals:

Show evidence of predicted diseases by CDSS.

-     Response from the XAI:

Evidence is the case data of this medical literature.

Technical background for XAI

The AI techniques used for implementation are as follows:

1)   Example-based explanations

2)   Surrogate model

3)   K-Nearest Neighbors

Based on the XAI requirements for CDSS, we selected these techniques.

Example-based explanations

Example-based explanations explain each predicted data.
The explanation is the identified instances of the training data contributing to the predicted data. (12)

The features of the Example-based explanations are as follows: (12)

1)   The simplest XAI method, with interpretability and explainability

2)   Explain predicted data by identifying instances of the training data contributing to it

3)   A mostly model-agnostic

4)   Available only if a human can understand the instance's contents

The case data of CDSS is obtained from the medical literature.
If it can identify instances of the training data (= case data), it can show evidence of the predicted data
(= predicted diseases).

However, the Neural Network (NN) using the CDSS's prediction model is not adapted to Example-based
explanations.

Surrogate model

The (local) surrogate model explains each predicted data of the main model. (12)

The differences between the main and surrogate models are as follows: (12)

1) The main model is often uninterpretable (black box).

2) The surrogate model is an interpretable and explicable (white box) model.

3) The prediction performance of the surrogate model is lower than that of the main model.

4) The surrogate model's predicted data is not equal to the main model.

K-Nearest Neighbors

The features of the k-Nearest Neighbors (k-NN) are as follows:

1) The simplest AI method, with interpretability and explainability

2) Support Example-based Explanations by instances of the training data

3) Wide adaptability

a) Non-parametric supervised learning method

b) Pattern matching

c) Various distance and evaluation functions

d) High-dimensional data (ex: varieties of symptoms and diseases)

e) Scarce training data (ex: rare diseases and cases)

4) Prediction performance is lower than that of the NN

k-Nearest Neighbors Surrogate model for Clinical Decision Support System

We propose the k-Nearest Neighbors Surrogate model (k-NN Surrogate model) as the XAI model for
CDSS.

Requirements of CDSS and features of k-NN are remarkably adaptable, except for the k-NN's prediction
performance.
Requirements of XAI for CDSS and features of Example-based explanations are remarkably adaptable.
The k-NN Surrogate model is a symphony of Example-based explanations, Local surrogate model, and k-
NN.
It improves prediction and XAI performance by "Selecting its data closest to the main model."

In a typical k-NN use case, the number of neighbors (k) is selected by hyperparameter optimization
during the design phase. The value of k is fixed during the prediction phase.

In the k-NN Surrogate model, the value of k is changed for each prediction. It predicts multiple data with
multiple numbers of neighbors (ex: $k = 1 - 10$). The value of closest k ($k\_closest$) is selected by the
evaluation function's value between the main model's predicted data and the surrogate model's
multiple predicted data. This process can closest the surrogate model's predicted data to the main
model. (defined as "Selecting" from now on)

By "Selecting," the surrogate model's data (the predicted data and instances of them) are good
surrogates for the main model.

k-NN Surrogate model can show evidence of the predicted diseases to medical professionals.

Implementation

Definitions of data

(See**:** Table 1**)**

Table 1 Definitions of data

Variables, Functions, etc.	Definitions
Case data	
X_train	Training data for features
y_train	Training data for targets
X_test	Test data for features
$y\_test\ (y\_true)$	Test data for targets (True data for targets)
User's input	
X_in	User's Inputted data
Main model	
$y\_pred = main\_model.prdict(X)$	The main model's predicted data
$ndcg\_nn = ndcg(\boldsymbol{y\_true}, \boldsymbol{y\_pred})$	The main model's prediction performance
Surrogate model	
$k = 1 - 10$	The number of neighbors
$y\_pred\_k[] = surrogate\_model.predict(X, k)$	The surrogate model's predicted data
$ndcg\_k1[] = ndcg(\boldsymbol{y\_true}, \boldsymbol{y\_pred\_k}[])$	The surrogate model's prediction performance
$ndcg\_k2[] = ndcg(\boldsymbol{y\_pred}, \boldsymbol{y\_pred\_k}[])$	The surrogate model's XAI performance
$k\_closest = argmax(ndcg\_k2[]) + 1$	Selecting the surrogate model's predicted data closest to the main model
$ndcg\_k1\_closest = ndcg\_k1[k\_closest - 1]$	The surrogate model's prediction performance with "Selecting"
$ndcg\_k2\_closest = ndcg\_k2[k\_closest - 1]$	The surrogate model's XAI performance with "Selecting"

Medical literature, metadata, and case data

Medical literature

Medical literature is a source of metadata and case data. It includes medical textbooks, original articles,
case reports, etc. It will be selected carefully for the purposes of the CDSS. It is limited to clear sources
and peer-reviewed content.

Metadata

Metadata is obtained from the medical literature by text-mining. It includes bibliographic, disease-
related, and other information.

Case data

Case data is obtained from the metadata by coding. It is used as training and test data for models. It
includes symptoms and diseases.
Symptoms include signs and symptoms, laboratory and imaging test results, etc.
Diseases include confirmed diseases, differential diseases, and their scores.
Case ID can identify and cross-reference between the metadata and the case data. (See: Table 2, Fig 2)

Table 2 Example of metadata and case data

Environments for development and execution

The evaluation function for the main (NN) and surrogate (k-NN) models is the Normalized Discounted
Cumulative Gain ($ndcg$).
The loss function for the main model (NN) is the approximate NDCG loss ($A - NDCG$). (19) (See: Table 3,
Table 4)

Results and Discussion

Prediction performance

The prediction performance of the main and surrogate models was evaluated. (See: Table 5)

Table 5 Prediction performance of the main and surrogate models)

Models	Data	k	$ndcg$	$ndcg$@1	$ndcg$@3	$ndcg$@5	$ndcg$@10
Main	$ndcg\_nn$	----	0.6684	0.4609	0.5393	0.5690	0.5988
Surrogate	$ndcg\_k1[]$	1	0.5348	0.3417	0.3782	0.3986	0.4231
		2	0.5636	0.3444	0.4122	0.4366	0.4632
		3	0.5738	0.3554	0.4201	0.4467	0.4754
		4	0.5784	**0.3597**	**0.4242**	**0.4517**	0.4810
		5	0.5791	0.3587	0.4240	0.4514	**0.4812**
		6	**0.5791**	0.3581	0.4222	0.4510	0.4812
		7	0.5778	0.3526	0.4206	0.4484	0.4797
		8	0.5772	0.3510	0.4190	0.4480	0.4788
		9	0.5756	0.3487	0.4165	0.4451	0.4766
		10	0.5735	0.3440	0.4137	0.4421	0.4740
	$ndcg\_k1\_closest$	----	0.6264	0.4361	0.4930	0.5158	0.5385

The "standalone" surrogate model's prediction performance is lower than the main model.
When "Selecting," the surrogate model's prediction performance is higher than the "standalone"
surrogate model.
However, it is lower than the main model.

XAI performance

The XAI performance of the surrogate model was evaluated. (See: Table 6)

Table 6 XAI performance of the surrogate model

Model	Data	k	$ndcg$	$ndcg@1$	$ndcg@3$	$ndcg@5$	$ndcg@10$
Surrogate	$ndcg\_k2[]$	1	0.8049	0.6526	0.5975	0.5900	0.5994
		2	0.8255	0.6775	0.6521	0.6415	0.6429
		3	0.8335	0.6912	0.6674	0.6601	0.6600
		4	0.8381	0.7016	0.6763	0.6690	0.6698
		5	0.8403	**0.7040**	0.6800	0.6731	0.6748
		6	0.8414	0.7033	0.6812	0.6755	0.6775
		7	0.8421	0.7038	0.6828	0.6770	0.6790
		8	0.8424	0.7019	**0.6831**	0.6775	0.6796
		9	**0.8426**	0.7012	0.6829	**0.6776**	**0.6801**
		10	0.8422	0.6979	0.6812	0.6768	0.6798
	$ndcg\_k2\_closest$	----	0.8800	0.8654	0.8101	0.7810	0.7566

XAI performance is the similarity between the predicted data of the main and surrogate models. The similarity is evaluated by the evaluation function.

The "standalone" surrogate model's XAI performance is high.

When "Selecting," the surrogate model's XAI performance is higher than the "standalone" surrogate model.

"Selecting data closest to the main model" improves the surrogate model's prediction and XAI performance.

Conclusions

The k-NN Surrogate model is a useful XAI model for CDSS.

It is a symphony of Example-based explanations, Local surrogate model, and k-NN.

k-NN is adapted to high-dimensional data (ex: varieties of symptoms and diseases) and scarce case data (ex: rare diseases and cases).

Our CDSS's case data are the same as evidence in the medical literature.

For CDSSs with similar aims and features, Example-based explanations are helpful and easy to implement. The k-NN Surrogate model is an Evidence-based XAI for CDSS

Uncertainty Quantification (UQ) is an essential issue for AI and CDSS. (20), (21)

k-NN is adapted to Conformal Prediction (CP), one of UQ's. (22), (23)

The k-NN Surrogate model will also contribute to these improvements in performance.

Unlike current commercial Large Language Models (LLMs), Our CDSS shows evidence of the predicted diseases to medical professionals.

This emphasis on evidence provides a sense of reassurance and confidence in the system's capabilities.

It is important to remember that XAI and the k-NN Surrogate model are beneficial and can change the game for CDSSs.
