Abstract

Two recent studies suggested that the *APOE* ε4 haplotype was associated with increased α-synuclein pathology in cell and mouse models. Genetic variants in the *SNCA* region have strong association with Parkinson's disease (PD), Dementia with Lewy Bodies (DLB), and idiopathic REM Sleep Behavior Disorder (iRBD), while *APOE* is a genetic risk determinant for only DLB. To determine if genetic-level interactions between *SNCA* and *APOE* exists that can explain the protein-level association, we investigated the genotypic interaction of *APOE* and *SNCA* in cohorts of PD, DLB, and iRBD. We analyzed genome-wide association study (GWAS) data from 5,229 PD patients and 5,480 controls, 2,610 DLB patients and 1,920 controls, and 1,055 iRBD patients and 3,667 controls. We used logistic regression interaction models across all 3 cohorts independently between the 1) top GWAS signals of *SNCA* SNPs and *APOE* haplotypes, 2) SNP x SNP and 3-way SNP interaction across the entire coding region plus 200kb flanking each gene. No significant interactions were found to be associated with any of the synucleinopathies after correction for multiple testing. Our results do not support a role for genetic interactions between *APOE* and *SNCA* across PD, DLB, and iRBD. Since the tested genetic variants affect the expression and function of these proteins, it is likely that any interactions between them does not affect the risk of PD, DLB and iRBD.

Keywords: Parkinson's Disease, Synucleinopathies, Dementia with Lewy Bodies, REM Sleep Behavior Disorder, Alzheimer's Disease, APOE, SNCA, synuclein, epistasis

1. **Introduction**

   Alpha-Synucleinopathy is an umbrella term to describe several neurodegenerative diseases that have a common defining pathological feature, characterized by neuronal or glial inclusions of aggregated alpha-synuclein, known as Lewy bodies, Lewy neurites or glial cytoplasmatic inclusions in the brain[1]. Disorders that are collectively referred to as alpha-synucleinopathies include Parkinson's disease (PD), Dementia with Lewy Bodies (DLB) and multiple system atrophy (MSA). Furthermore, there is an increased presence of alpha-Synucleinopathy in the prodromal condition idiopathic/isolated REM sleep behavior disorder (iRBD), which can convert to either PD, DLB or MSA in more than 80% of cases[2].

   Alpha-synuclein is encoded by the *SNCA* gene, and genetic variants in the *SNCA* locus are associated with PD, DLB and iRBD risk in genome-wide association studies (GWASs)[3-8]. Specifically, some variants of *SNCA* are strongly associated with PD (rs356182 and rs2870004), while others are associated with DLB (rs7681440 and rs7680557)[7,9] and iRBD (rs2870004)[10]. The top *SNCA* association in PD is independent and different than the top associations in DLB[7] and iRBD[8], raising the hypothesis that there could be differential effects of *SNCA* variants on the expression of alpha-synuclein in different brain regions[8].

   Overlapping neuropathologic features associated with Alzheimer's disease (AD) are seen in the brains of many patients with PD[11] and dementia including amyloid plaques composed of amyloid-beta (Aβ) plaques and neurofibrillary tangles containing the tau protein and may contribute to clinical features of disease[12,13].

   Coding variants in apolipoprotein E (*APOE*) produce 3 common alleles, ε2, ε3, and ε4. The *ε4* allele of *APOE* regulates lipid metabolism and cholesterol transport and known to be a major genetic risk determinant for sporadic, late-onset Alzheimer's Disease[14] and Lewy Body

Dementia[7,9]. Dose effects by allele have demonstrated a 3.7-fold risk of developing AD while homozygosity increases the risk by up to 12-fold[7]. From numerous GWASs, A*POE* does not alter the risk for PD, yet the ε4 allele has been described as a potential risk factor for cognitive decline and development of dementia in PD patients[15,16].

Two studies in mice demonstrated that the APOE*ε4 genotype was associated with increased alpha-synuclein pathology, independent of the amyloid β deposition[17,18]. These two studies emphasize a potential molecular mechanism of APOE*ε4 on α-Synuclein protein aggregation. However, beyond A53T, they have not evaluated disease specific variants of *SNCA* that have functional molecular consequences (*e.g.* E46K)[19]. Analysis of these variants could be insightful in understanding molecular association between *SNCA* variants and APOE*ε4. Furthermore, while the *SNCA* locus is associated with all synucleinopathies, *APOE* is a genetic risk factor for DLB only. *SNCA* and *APOE* variants may affect the expression / function of the proteins encoded by them[20]. Therefore, if a true interaction exists at the protein level as suggested by the studies mentioned above, then there plausibly should be evidence of some association at the genetic level.

Genetic interactions refer to a combination of two or more genetic variants whose phenotypic contribution is amplified by their co-occurrence[21]. To determine if genetic-level interactions between *SNCA* and *APOE* exist that can explain the protein-level association as described, we investigated the genotypic interaction of *APOE* and *SNCA* in three disease cohorts of PD, DLB and iRBD patients and controls, with a total of 8,855 patients and 11,067 controls.

2. Methods

Patient population: For PD, we used the International Parkinson's Disease Genomics Consortium (IPDGC) data set that contained 10,709 subjects with 5,229 cases and 5,480 controls. For DLB, we used the most recent DLB GWAS dataset which included 4,530 subjects with 2,610 cases and 1,920 controls. The iRBD cohort was composed of 4,742 individuals, including 1,055 cases and 3,667 controls with 1,968 controls from NGRC, (dbGAP: phs000196.v2.p1) and 790 controls from NIND (dbGAP: phs000089) added from external studies of Parkinson's patients in addition to the controls collected for the iRBD cohort. PD was diagnosed using UK Brain Bank criteria or Movement Disorders Society (MDS) criteria[4]. DLB patients were diagnosed with pathologically definite or clinically probable disease according to consensus criteria[22]. iRBD was diagnosed according to the International Classification of Sleep Disorders (2nd or 3rd Edition)[23,24]. Informed consent and ethics approval was obtained from the appropriate institutional review boards at participating institutions as described in the original studies.

Genetic Analysis: We generated genotype calls of two *APOE* SNPs, rs429358 and rs7412 to determine the *APOE* haplotype status of each sample. The combination of genotypes for rs429358 (C/T) and rs7412 (C/T) defines the three *APOE* haplotypes: epsilon 2 (ε2), epsilon 3 (ε3), and epsilon 4 (ε4). These three haplotypes can produce six genotypes, ε2/ε2, ε2/ε3, ε2/ε4, ε3/ε3, ε3/ε4, and ε4/ε4, whose frequency amongst the cohorts is detailed in Table 2. Cohorts were collected, quality controlled, genotyped and filtered on individual and variant-level as previously described for PD[4] , iRBD[8], and DLB[7]. *APOE* variants were analyzed for the 200kb region flanking both sides on chromosome 19: 44,705,791 - 45,109,393 and for

SNCA on chromosome 4: 89,500,345 - 90,038,324. For the iRBD cohort, additional cohorts of control subjects added from NIND and NGRC were included. The DLB genotypic data was converted from GrCh38 to GrCh37 using Liftover[17]. Because external controls were added to the iRBD cohort; the cases and control genotypes were filtered for minor allele frequency (MAF) > 0.01 to reduce imputation errors and imputed using Michigan Imputation Server and the Haplotype Reference Consortium[18] r1.1 2016 reference panel (GRCh37/hg19). Only imputed genotypes with an $R^2 > 0.30$ were kept for analysis. Additionally, prior to analysis further quality control for each cohort included removing duplicate samples, missing data including covariates; SNPs were filtered based on variant missingness (< 0.05), genomic relatedness (> 0.125), disparate missingness between cases and controls ($p > 1E-04$), missingness by haplotype ($p > 1E-04$), deviation from Hardy-Weinberg equilibrium ($p > 1E-04$), minor allele frequency (MAF) > 0.01, and LD pruned with r^2 at >0.5 with a 50kb window using plink 1.9 [19].

Statistical Analysis: Descriptive measures of mean, standard deviations, frequencies, and percentages were used to summarize the data. SNP and haplotype interaction were analyzed using logistic regression controlling for age, sex and ancestry using the first five principal components. Epistasis model was defined as

$$Y \sim \beta_0 + \beta_1 A + \beta_2 B + \beta_3 AB + \epsilon$$

where β_0 represents the intercept, β_n represents the coefficients for each SNP, and A and B represent allele dosage of each SNP and AB represents the interaction. The test for interaction was based on the coefficient β_3 and P-value<0.05 as significant when testing interaction between top SNPs, and Bonferroni threshold applied for SNP x SNP interactions. Detecting

gene-gene interactions in complex diseases can be accomplished using a variety of epistasis-focused tools or packages in existing software packages. Model- based Multifactor Dimensionality Reduction (MB-MDR) was implemented as a final screen strategy to detect any significant SNP x SNP and SNP x SNP x SNP interactions using the open-source MB-MDR v 4.4.1 software, as MB-MDR merges multi-locus genotypes exhibiting some significant evidence of High or Low risk, based on association testing into a new lower-order dimension. A new association test is subsequently performed per marker pair/triplet, by adopting a permutation-based strategy that corrects for multiple testing (over all marker pairs/triplets) and adequately controls family-wise error rate at $\alpha=5\%$[20].

3. **Results**

To explore possible interactions between *APOE* and *SNCA* in cases and controls, we first focused primarily on the top *SNCA* SNPs associated with PD, DLB, and RDB (Table 1) and the *APOE* haplotypes. We performed a SNP-haplotype logistic regression interaction controlling for age, sex and ancestry using the first five principal components. No significant interactions were found to be statistically significant (Table 1).

To further explore all potential genetic interactions between *APOE* and *SNCA*, we expanded the range to include all SNPs in *APOE* and *SNCA* plus 200kb outside the region ends on both genes across all cohorts. We pruned SNPs that were in LD with an r^2 of 0.5 with 316 SNPs remaining in PD; 421 SNPs remaining in DLB; and 198 SNPs remaining in iRBD. We applied PLINKs regression-based approach to model and test SNP x SNP interactions. After correction for multiple comparisons with a Bonferroni correction, we did not identify any interactions associated with any of the alpha-synucleinopathies (Table 3).

Lastly, a model-based Multifactor Dimensionality Reduction method was implemented as a final screen strategy to detect any significant SNP x SNP and SNP x SNP x SNP interactions using the open-source MB-MDR software[21]. Here too, no significant interactions were found to be associated with PD, DLB or iRBD after correction for multiple testing using permutation testing across all three cohorts (Supplementary Tables S1-S3).

4. **Discussion**

Our results do not support a role for genetic interactions between *APOE* and *SNCA* across PD, DLB, and iRBD. The genetic variants that were tested influence the expression and function of these proteins, but it is unlikely that any interactions between them affect the risk of developing synucleinopathies. Although functional epistasis, in the form of biomolecular interaction, can determine biological pathways of disease progression, it may not always be detected through mathematical or statistical genetic interaction analyses. Furthermore, the genetic interactions identified in our study, which represent three synucleinopathies, do not support the pathological associations observed in model organisms intended to represent these disease populations.

Previous studies have shown that APOE ε4 is linked to DLB in both AD and non-AD cases [22,23]. However, some studies have also shown that APO ε4 is only associated with DLB when there is a significant amount of co-existing Alzheimer's pathology [24-26]. This finding contradicts the idea that APO ε4 independently drives α-synuclein pathology.

This study has several limitations. The lack of pathological confirmation of Lewy Bodies and AD pathology in the cohorts does not allow for an analysis based on co-pathology. Such analysis would have been able to detect interactions that exist only in subpopulation of patients, for example those who have both alpha-synuclein and amyloid pathology. Another limitation

is that the study scope was limited to *APOE* and *SNCA*. Recently, a stratified GWAS of DLB uncovered an association only between *GBA* rs2230288 and pathologically confirmed DLB without AD pathology, but not in mixed pathological cases [26]. This same SNP has been identified as a significant risk variant in the most recent GWAS of DLB [7]. It is possible that large scale GWAS would uncover associations that encompass a broad spectrum of disease (e.g. DLB with no AD pathology, DLB with mixed PD and AD pathology etc.), even though these associations may be driven by subsets of these genetic loci (e.g *GBA*). Furthermore, it is plausible that different disease subtypes consist of distinct genetic combinations and interactions that have not yet been identified at a population level due to the limited size of current sample cohorts. Further studies should include more samples and implement alternative statistical or interrogative methods to leverage the current data to its fullest potential despite its small sample size.

Data Availability

The data that support the findings of this study are available from dbGaP. Parkinson's patients and controls (phs000918.v1.p1). DLB patients and controls are available from dbGaP (phs001963.v1.p1). iRBD patients and controls are available upon reasonable request from the corresponding author. Additional controls were also obtained from dbGaP; NGRC (phs000196.v2.p1) and NIND (phs000089). Code used for analysis can be found on GitHub (https://github.com/gan-orlab/APOE_SNCA)

Acknowledgements

We would like to thank all the participants in the different cohorts. We would also like to thank all members of the International Parkinson Disease Genomics Consortium (IPDGC). See for a complete overview of members, acknowledgements, and funding http://pdgenetics.org/partners.

Funding

This work was financially supported by the Michael J. Fox Foundation and the Canadian Consortium on Neurodegeneration in Aging (CCNA). Table 1: Age and sex of each cohort in cases and controls.

Demographic			Total		PD		DLB		iRBD
Sex	*Cases*	*Male (%)*	5845 (65.72)		3366 (64.37)		1642 (62.91)		837 (79.34)
		Female (%)	3010 (33.84)		1863 (35.63)		947 (36.28)		200 (18.96)
	Controls	*Male (%)*	7256 (65.56)		3055 (55.75)		972 (50.63)		1564 (42.65)
		Female (%)	3811 (34.44)		2425 (44.25)		948 (49.38)		2103 (57.34)
Age	*Cases*		65.7 (13.6)		61.2 (12.6)		74.7 (10.5)		-
	Controls		67.9 (16.2)		64.3 (14.8)		72.7 (16.8)		-

Values for age represent mean and standard deviation in parenthesis. Age information for iRBD was missing

Abbreviations: PD, Parkinson's Disease; DLB, Dementia with Lewy Bodies; iRBD, Idiopathic Rapid Eye Movement (REM) sleep behavior disorder.

Table 2: *APOE* Haplotype Frequencies of each cohort in cases and controls

Group	Haplotype	Controls	Cases	Total
DLB	e2e2	4 (.21)	5 (.19)	9
	e2e3	171 (8.91)	189 (4.17)	360
	e2e4	17 (.89)	83 (3.18)	100
	e3e3	1273 (66.30)	1203 (46.09)	2476
	e3e4	419 (21.82)	916 (35.10)	1335
	e4e4	36 (1.88)	214 (8.20)	250
	Total	**1920 (42.38)**	**2610 (57.62)**	**4530**
iRBD	e2e2	22 (.61)	5 (.48)	27
	e2e3	444 (12.27)	109 (10.4)	553
	e2e4	82 (2.27)	15 (1.43)	97
	e3e3	2241 (61.92)	671 (64.03)	2912
	e3e4	752 (20.78)	236 (22.52)	988
	e4e4	78 (2.16)	12 (1.15)	90
	Total	**3619 (77.54)**	**1048 (22.46)**	**4667**
PD	e2e2	41 (.75)	25 (.48)	66
	e2e3	725 (13.23)	656 (12.55)	1381
	e2e4	106 (1.93)	75 (1.43)	181
	e3e3	3599 (65.68)	3498 (66.90)	7097
	e3e4	954 (17.41)	932 (17.82)	1886
	e4e4	55 (1.00)	43 (.82)	98
	Total	**5480 (51.17)**	**5229 (48.83)**	**10709**

Values represent frequency and percentage.
Abbreviations: PD, Parkinson's Disease; DLB, Dementia with Lewy Bodies; iRBD, Idiopathic Rapid Eye Movement (REM) sleep behavior disorder.
