Economics of Harm Reduction.

Key points (95/100 words)

Question: What was the effect of overdose prevention sites and supervised consumption sites (OPS/SCS)
on crime in Toronto?

Findings: Pooled site- and neighbourhood-level random effects models found counts of break and enters
increased, but trends in outcomes declined per month. Trends in assaults, robberies, thefts over $5000,
bicycle thefts, and thefts from motor vehicles also decreased. Site- and neighbourhood-specific
interrupted time series showed some communities were impacted negatively while others were not.

Meaning: The effects of Toronto's OPS/SCS on crime were generally neutral to positive; break and
enters increased immediately post-implementation, but declined with time.

Abstract (342 words / 350 words)

Importance: Beginning in August 2017, nine overdose prevention sites and supervised consumption sites
(OPS/SCS) began operating in Toronto, Canada. Following years of community pushback that these sites
increased local crime and disorder, they were closed in March 2025.

Objective: To evaluate the population-level effects of OPS/SCS on crime and disorder.

Design, Setting, Participants: This two-part ecological study used Toronto Police Service data to
compare crime incidence before and after OPS/SCS implementation using interrupted time series analyses
with and without controls. We restricted analysis to crimes that occurred within city boundaries between 1
January 2014 and 30 June 2024.

Main Outcomes and Measures: We used monthly event counts of all assaults, auto thefts, break and
enters, robberies, thefts over $5000, bicycle thefts, thefts from motor vehicle and mental health
apprehensions as our eight outcomes. We compared incidence within 100m, 200m, and 400m of the
geolocation of each OPS/SCS before and after implementation; and repeated analysis using treated and
synthetic control neighbourhoods. We pooled estimates for population-level effects.

Results: Within 400m (approximately a quarter mile), we observed level effects for break and enters
(48.87%, 95% CI: 26.15, 75.68%) and bicycle thefts (-19.46%, 95% CI: -30.36, -6.86%) immediately
post-implementation. Meanwhile, monthly trends for assaults (-0.5%, 95% CI: -0.92, -0.07%), break and
enters (-1.11%, 95% CI: -1.60, -0.61%), robberies (-1.36, 95% CI: -1.96, -0.75%), thefts over $5000 (-
1.47%, 95% CI: -2.92, 0.01%), bicycle thefts (-1.54%, 95% CI: -2.44, -0.62%), and thefts from vehicles (-
1.59%, 95% CI: -2.58, -0.60%) declined. Pooled neighbourhood analyses showed level-effects for break
and enters (18.83%, 95% CI: 1.70, 38.84%) and mental health apprehensions (10.20%, 95% CI: 1.55,
19.60%) post-implementation; and monthly changes in trends for break and enters (-0.46%, 95% CI: -
0.93, 0.01%), auto theft (-0.66%, 95% CI: -1.31, 0.00%), thefts over $5000 (-1.02%, 95% CI: -2.05,
0.03%), and bicycle thefts (-1.07%, 95% CI: -1.58, -0.57%). Site- and neighbourhood-specific results
revealed some communities were impacted while others were not.

Conclusions and Relevance: The effects of Toronto's OPS/SCS on crime were generally neutral. Break
and enters increased immediately post-implementation, but declined with time.

Key words: harm reduction, supervised consumption sites, public health, crime, neighbourhoods

Data Sharing Agreement

This study used publicly available data provided by Toronto Police Services. For more information, please visit the Toronto Police Service Public Safety Data Portal at: https://data.torontopolice.on.ca/. For Statistics Canada census tract profiles visit: https://www12.statcan.gc.ca/census-recensement/2021/dp-pd/prof/index.cfm?Lang=E.

Introduction (405 words)

Canada's largest city, Toronto, has been hit hard by the ongoing opioid crisis. Since 2016 there have been over 3,251 opioid-related deaths; and in 2021 the death rate exceeded 19.4 deaths per 100,000,[1] putting it on par with cities like New York, Houston, San Diego, Las Vegas, and Seattle.[2] As part of the city's harm reduction strategy, nine overdose prevention sites (OPS) and supervised consumption sites (SCS) were implemented between 2017 and 2018. Despite evidence demonstrating the health benefits of OPS/SCS for people who use unregulated drugs,[3,4] these sites remain controversial. Critics argue OPS/SCS may increase local crime by attracting drug-related activity such as theft, assault and open drug use.[5]

Early evidence following the implementation of Vancouver's Insite (2003), and Sydney's Medical Injecting Centre (2001) found no changes in police-recorded thefts or robberies, drug possession, drug dealing, open drug use or assaults.[8-10] More recently, a study examining the effects of an unsanctioned SCS in the United States reported assault, burglary, larceny theft, robbery and drug related incidents declined in the treated neighbourhood but remained the same in two control communities.[11] Similarly, a study examing the effects of New York's two overdose prevention sites observed no significant effects on counts of violent or property crimes, in aggregate.[12] However, the study did reveal a 30.4% (95%CI: 10.4, 54.0%) increase in aggravated assaults, and a 69.1% (95%CI: 18.3, 141.7%) increase in vehicle thefts offset by the 34.9% (95%CI: -54.0, -7.8%) decline in robberies. Meanwhile, a second study of New York's sites found differential effects of the SCS owing to plausible moderating factors including a 'target of opportunity' for petty larceny near one site but not the other.[13]

While many studies indicate SCS do not increase neighbourhood crime and may reduce public drug use, differences in the methods used and their respective limitations may explain the variations in outcomes reported. These include short observation periods and the inability to detect meaningful differences in crime trends over time, aggregating crimes to improve statistical power but losing nuance, and not adjusting for local population demographics. Further, many of the studies dominating the literature are specific to well-resourced sites and, in the case of Vancouver's Insite, set up as a pilot to demonstrate feasibility and impact.[14] Given the ongoing equipoise, and local arguments opposed to the continued operation of Toronto's sites, we evaluated the effects of the city's nine OPS/SCS on neighbourhood crime and mental health act apprehensions using publicly available data.

Method (833 words)

Study design

For this ecological study, we used interrupted time series analyses with and without synthetic controls.

Setting

Toronto is an ethno-racially diverse city with approximately 2.8 million residents. [15][16] Between 1990 and

2022, the city was divided into 140 neighbourhoods with unique demographics and social service needs.

Each neighbourhood is comprised of multiple, contiguous Statistics Canada census tracts.[17] Although

some neighbourhoods were redefined to reflect demographic and density changes in spring 2022, we refer

to the original 140 neighbourhood boundaries in our study. Beginning in 2017, the majority of opioid

poisoning calls were observed to be concentrated in downtown neighbourhoods.[18] In response, the

Overdose Prevention Society opened the first unsanctioned OPS in Moss Park in August 2017 and within

a year, nine OPS/SCS were in operation (Supplement Table 1).

Data

We restricted analysis to founded crimes that occurred between 1 January 2014 and 30 June 2024 as

reported in four publicly available Toronto Police Service datasets: Major Crime Indicators (MCI),

Bicycle Thefts, Theft from Motor Vehicle, and Mental Health Act Apprehensions (Supplement Table 2 for

definitions). The MCI included records for five major crimes: assaults, auto thefts, break and enters,

robberies, and thefts over $5000. Across all four datasets, each incident record included a unique

identifier, date of occurrence, and the name and numeric identifier of the neighbourhood. Apart from

mental health act apprehensions, the remaining three datasets also included geo-coordinates of the

intersection closest to the event location.

Analysis

We conducted two sets of analysis to overcome the limitations observed in other studies. First, we

conducted site-specific interrupted time series (ITS) analysis with segmented negative binomial

regression to test for level and trend changes on counts of crimes within 100m, 200m and 400m (i.e.,

approximately a quarter mile) of the nine OPS/SCS: $outcome_{jt} = \beta_0 + \beta_1 \cdot time_t + \beta_2 \cdot level_j + \beta_3 \cdot trend_{jt} + \varepsilon_{jt}$,

where β_1 is the underlying trend in the outcome across time, β_2 captures the level effect immediately post-

implementation, and β_3 represents the trend effect following the implementation of the local OPS/SCS

relative to the underlying trend. To avoid double counting events that occurred within the radii of

observation of two sites (e.g., Fred Victor site opened within 400m of Moss Park OPS) we only assigned

events that occurred outside the first site's radius to the new site. We set the month of implementation as

time zero, and reported monthly sums of outcomes.

We repeated the analysis comparing outcome counts in treated neighbourhoods with synthetic controls to

account for neighbourhood-level demographic differences. We linked Toronto Police Service records with

2011, 2016, and 2021 census tract profiles using their respective year of incidence and boundary files for

point-in-polygon spatial joins, and created neighbourhood demographic profiles by weighting the census

tracts that fell within each neighbourhood's boundaries.[19] For each, treated neighbourhood we made a

synthetic control neighbourhood using the pool of neighbourhoods that never implemented an OPS/SCS

during our observation period and whose boundaries were > 400m of any OPS/SCS.[20] In creating

synthetic controls, we accounted for population size and density, proportion of females, distribution of

age (0-14, 15-64, and 65+) and average age, average household size, median income, prevalence of low-

income households after tax, unemployment rate, and proportion of lone-parent households, immigrants,

visible minorities, and individuals without high school diploma or equivalent certificate.

We used controlled interrupted time series analysis with segmented negative binomial regression to

compare the level and trends of crime and mental health act apprehension counts observed in treated

neighbourhoods vs. synthetic controls post-implementation: $outcome_{jkt} = \beta_0 + \beta_1 \cdot time_t + \beta_2 \cdot group_k + \beta_3 \cdot$

$group_k \cdot time_t + \beta_4 \cdot level_{jt} + \beta_5 \cdot trend_{jt} + \beta_6 \cdot level_{jt} \cdot group_k + \beta_7 \cdot trend_{jt} \cdot group_k + \varepsilon_{jkt}$ where β_1 is the

underlying trend in the outcome observed in the synthetic control group, β_2 is the level difference pre-

intervention between the treated and synthetic control group, β_3 represents the difference in trend between

the treated and synthetic control group *before* the intervention is implemented, β_4 is the level change in the

synthetic control group post-implementation compared with immediately before the intervention's

implementation, β_5 is the trend change for the synthetic control post-implementation, β_6 is the level

change of the treated group *relative* to the synthetic control group change observed post-implementation,

and β_7 is the trend change in the treated group *relative* to the synthetic control group post-implementation.

For both sets of models, we included four harmonic terms to capture seasonal effects, and used Newey-

West standard errors with lag of 3 to account for data heteroscedasticity and residual autocorrelation. For

overall effects, we pooled site- and neighbourhood-specific ITS outcomes and reported random effect

estimates owing to the varying between-site heterogeneity.

All data preparation and analyses were conducted using R version 4.3.1 in R studio, with packages

geosphere, AICcmodavg, tidyverse, sf, Synth, crsuggest, cancensus, foreign, tsModel, lmtest, Epi, splines,

vcd, sandwich, reshape2, SCtools, janitor, gdata, rlang, tidyselect, car, and nlme**.**

Ethics

This study used publicly available data and was exempt from ethics review by McGill's institutional

review board.

RESULTS (480 words)

After removing duplicates, errors, and incidents that occurred outside city boundaries, 172,681 assaults,

56,414 auto thefts, 71,255 break and enters, 26,180 robberies, 12,528 thefts over $5000, 29,128 bicycle

thefts, 92,803 thefts from motor vehicles, and 110,387 mental health act apprehensions occurred within

Toronto during the observation period. Of these, 21,705 (12.6%) assaults, 1,805 (3.2%) auto thefts, 6,808

(9.6%) break and enters, 4,103 (15.7%) robberies, 1,085 (8.7%) thefts over $5000, 5,586 (19.2%) bicycle

thefts, and 8,286 (8.9%) thefts from motor vehicles occurred within 400m of the OPS/SCS locations.

Figure 1 summarizes the results of our site- (400m) and neighbourhood-specific analyses. For additional

information on sites, their implementation dates, and locations; along with the creation of synthetic

controls and results at 100m and 200m see Supplement.

In pooled analysis, within 100m of OPS/SCS, there were no statistically significant level or trend effects

in incidents of assaults, robberies, auto thefts, bicycle thefts, or thefts from motor vehicles. There were no

level effects for break and enters, and thefts over $5000; but monthly trends declined 2.61% (95%CI: -

4.49, -0.68%) and 3.57% (95%CI: -6.87, -0.14%), respectively.

Within 200m, the lack of observed level or trend effects for assaults, auto thefts and thefts over $5000

persisted. There were no level effects observed for robberies, bicycle thefts, and thefts from motor

vehicles; but trends declined 1.76% (95%CI: -2.54, -0.97%), 1.58% (95%CI: -2.71, -0.44%), and 1.60%

(95%CI: -2.89, -0.29%), respectively. Meanwhile, break and enters increased 63.59% (95%CI: 9.23,

145%) immediately post-implementation, while trends declined 1.3% (95CI: -2.05, -0.53%) per month.

Within 400m, the level and trend effects observed within 200m of sites persisted for break and enters,

robberies, auto thefts, and thefts from motor vehicles. Trends declined for assaults 0.5% (95%CI: -0.92, -

0.07%), and thefts over $5000 1.47% (95%CI: -2.92, 0.01). Bicycle thefts decrease 19.46% (95%CI: -

30.36, -6.86%) immediately post-implementation, and continued to decline 1.54% (95%CI: -2.44, -

0.62%) each month thereafter.

Neighbourhood analyses found no level or trend effects for assaults, robberies, or thefts from motor

vehicles. Break and enters increased 18.83% (95%CI: 1.70, 38.84%) immediately post-implementation

but declined 0.46% (95%CI: -0.93, 0.01%) month-to-month. Trends declined for auto thefts 0.66%

(95%CI: -1.31, 0.00%), thefts over $5000 1.02% (95%CI: -2.05, 0.03%), and bicycle thefts 1.07%

(95%CI: -1.58, -0.57%). Meanwhile, we observed a level increase in mental health act apprehensions

(10.20%, 95%CI: 1.55, 19.60%), with no trend effects.

Disaggregated results revealed differences in level and trend effects by site and neighbourhood. For

example, assaults within 400m of Moss Park OPS increased (i.e., level effect) post-implementation, but

decreased for both Parkdale Community Health Centre (CHC) and St. Stephen's sites. Meanwhile, break

and enters increased near The Works, Regent Park, and St. Stephen's sites. At the neighbourhood level,

assault trends increased for South Parkdale, Niagara, and Waterfront Communities, but declined for

Regent Park. A level increase in break and enters was only observed for Kensington-Chinatown, while

robbery effects were observed in Trinity-Bellwoods.

DISCUSSION (1129 words)

Our analysis revealed that OPS/SCS did not have a level or trend effect on counts of grand theft or crimes

against persons; and a protective effect on petty theft within 400m. The observed increase in break and

enters within 400m diminished with time. A lack of effect on grand theft may reflect the absence or non-

differential presence of organized criminal activity near OPS/SCS.[21] Grand theft relies on concerted

criminal networks targeting high value items; and is less sensitive to small sociodemographic changes at

the community-level such as increases in people who use unregulated drugs.[22] Conversely, changes in

break and enters indicate an increase in spontaneous crimes and may be a consequence of coupling desire

with the opportunity to execute said crimes.

Our results echo others' observations that, *overall*, OPS/SCS did not contribute to increases in crimes.[8,11-

13,23] To contextualize our results, we consider the plausibility of three alternate explanations for our

findings: the 'honey-pot' effect, increased policing, and changes in data collection.

The 'honey-pot' effect describes the phenomenon where an intervention attracts people and/or behaviours,

and may explain why break and enters increased near OPS/SCS immediately following implementation.[5]

However, this phenomenon cannot explain why the initial increases in incidence did not persist. One

reason may be that between March 2020 and August 2021 the city engaged in a massive displacement of

people experiencing homelessness as part of its COVID-19 public health response. During this time, the

city rented three large hotels (i.e., Bond, Edward Village, and Novotel) to provide temporary emergency

shelter, effectively moving approximately 1000 people to other neighbourhoods. Meanwhile, the

enforcement of stringent social distancing measures scaled down OPS/SCS services.[24] The dispersing of

clients to other neighbourhoods might explain the decline in spontaneous crimes. However, when

measures were lifted, crime near OPS/SCS did not rebound despite a return to pre-pandemic rates of

service use.[25]

Similarly, while increased police presence near OPS/SCS could explain some of the decline in

spontaneous crimes, this presents a paradox. Previous studies noted police presence undermines the social

acceptability of harm reduction interventions for people who use unregulated drugs.[26] However, outside

COVID-19 restrictions, there was no notable decline in client visits. Further, as far back as 2018, police

budgets grew slower and the workforce *decreased*.[27,28] The Toronto Police Service's Mental Health and

Addictions strategy launched in 2019 may help reconcile the shortages in the police workforce with

decreases in crime reports.[29] It is possible that by improving policing *quality*, crimes against persons,

petty theft, and break and enters decreased with minimal effect on OPS/SCS patronage, and warrants

investigation.

Finally, changes in the reporting or collecting of data may explain the decline in outcomes over time.

However, in 2017, police services and Statistics Canada worked together to amend the definition of

'founded' criminal incidents to include events for which there was no credible evidence the incident *did*

not take place.[30] This victim-centred revision first came into effect 1 January 2018; and studies have

associated it with 4 – 12% *increases* in counts of assault, petty theft, and fraud in subsequent years.[31]

While it is possible the public reported fewer crimes against persons near OPS/SCS – this seems unlikely

when looking at city-wide reporting patterns.[32]

Nevertheless, like Hall et al., 2024, our analysis also found crime did increase near some OPS/SCS and

neighbourhoods with multiple OPS/SCS (e.g., Moss Park and Church-Yonge) were most negatively

impacted.[13] The agglomeration of services, combined with unique geographic features may explain some

of the differences observed. For example, the Moss Park neighbourhood boundaries include or are within

400m of Moss Park OPS, Fred Victor Centre, and Regent Park community health centre. Moss Park also

includes housing and emergency shelter options for people experiencing homelessness. An influx of new

people using OPS/SCS may have constrained existing resources and created tensions with incumbents

resulting in an increase in assault reports. Meanwhile, St. Stephen's is situated in Kensington Market, a

neighbourhood full of small shops where opportunities to break and enter are higher than elsewhere in the

city. Efforts to minimize break and enters (e.g., modernizing doorways and security) as well as declines in

event reportings to prevent increases to insurance payments may *partially* explain the downward trend.

Limitations

We did not include all OPS/SCS operating during the observation period. We excluded Casey House and

shelters that provided services to residents only. Casey House became the first hospital to offer supervised

consumption services to inpatients in August 2021, and expanded services to outpatients in April 2022.

Because of differences in clientele, scope, duration of operation, and proximity to other sites – we

excluded Casey House to minimize potentially biasing our analyses. Similarly, we did not include shelters

which provided overdose prevention services to their residents, including the three temporary housing

units implemented during COVID-19 social distancing efforts, as these are qualitatively different from

OPS/SCS open to the public.

Further, we were not able to account for time-varying differential changes. For example, the observation

period overlapped with significant upheaval in the housing market which may have contributed to

differences in the degree of transient people experiencing homelessness in treated versus donor pool

neighbourhoods. Owing to data availability, this remains a potential source of bias in our results.

Finally, we did not investigate the effects of OPS/SCS on public drug use, needle and syringe debris,

graffiti or public defecation – concerns repeatedly mentioned by opponents of OPS/SCS.[33] While we

explored the possibility of including 311 calls in our study, we determined the quality of data insufficient

and prone to reporting bias.

Strengths

To our knowledge, this was the first study to evaluate the effects of multiple OPS/SCS implemented

across a large metropolitan area. Owing to the number of sites and time elapsed since their

implementation, we were sufficiently powered to examine the effects of OPS/SCS on a variety of

measures separately, over time, and within proximity to sites. By pooling effect estimates by site and

neighbourhood, we reduced the potential for unmeasured contemporaneous interventions biasing our

results. Our synthetic controls were well matched to treated neighbourhoods (see reported root mean

square prediction errors values in Supplement). We limited the risk of overfitting our models and

achieving spurious pre-treatment fit by restricting analysis to three years.[34] While imperfect matching

between treated and synthetic controls may bias results, we combined traditional synthetic control

methods with ITS to compensate for small differences in trends between treatment arms. By reporting the

pooled and neighbourhood-specific synthetic control outputs, the effects of imperfect matching were

made transparent, demonstrated to be minimal, and adequately managed using controlled interrupted time

series methods.[35] Further, by using exclusively open access data, and providing our code, we minimized

the possibility for data preparation or analytic errors and increased the transparency of our work. Lastly,

we considered other explanations for our observed effects and found the available evidence did not

support these alternate narratives.

PUBLIC HEALTH IMPACTS (124 words)

Our analysis revealed the implementation of Toronto's OPS/SCS had nuanced site- and neighbourhood-

specific effects. Overall, the interventions' impacts were neutral to positive over time. This does not

negate the increases in spontaneous crimes in some communities, but rather suggests efforts to improve

crime while encouraging use of OPS/SCS are possible. Still, local communities may perceive OPS/SCS

as harmful, associating them with disorder and increased drug use in public spaces.[36] This tension needs

to be addressed to ensure the long term acceptability and utility of OPS/SCS. Efforts to establish

relationships with local community stakeholders and to work collectively through challenges can build

goodwill and trust between OPS/SCS operators, clients and the public. Meanwhile, efforts to dismiss or

negate apprehensions can undermine the public health intervention.
