Associations between social capital and other living conditions among young Angolan women: A

cross-sectional study in three provinces

Abstract

Social support systems play a crucial role in promoting young women's well-being and their human rights fulfilment, not least in contexts where institutions are weak and socioeconomic and gender inequalities prevail. However, research on young women's social networks and trust in their benevolent function is scarce. This study attempts to reduce this knowledge gap by exploring young Angolan women's access to social capital and how it clustered and was associated with other living conditions. The data were derived from a cross-sectional study of 2,071 women, aged 18-24 years, from rural and urban areas in Huambo, Luanda and Lunda Sul provinces. The results included a univariate description of the participants socioeconomic and social capital characteristics stratified by province and residential area, an exploratory factor analysis of 17 social capital variables, and tests for associations between social capital factors and socioeconomic variables (literacy, household wealth, work and pregnancy), the latter measured by means of logistic regressions. The study revealed that the women in Luanda had generally better living conditions, those from Lunda Sul were worse off, and those from Huambo were often in between. The factor analysis' identification of structural, cognitive, and applied factors aligned well with established research. Literate and wealthier participants often had higher structural but less cognitive social capital. Social capital measures showed less variability compared to literacy and household wealth. The social capital factors were distributed and associated differently with the socioeconomic attributes based on location. The study highlights the intricate relationship between social capital and other living conditions, conditional on where women live. It draws attention to the need for further investigations into which social spheres young women perceive as supportive. The study emphasises the importance of analysing social capital domains separately, appreciating links to other resources and local uniqueness in social capital-enhancing interventions.

Introduction

The importance of social capital for health and development at the individual and population levels has been demonstrated in numerous empirical studies [1-4]. According to this research, social capital facilitates cooperation between people and plays a vital role in the ability of societal institutions to cater to diverse groups. It has been found to be positively associated with increased self-rated health [5] and life satisfaction [6,7]. In addition, it has a bearing on who receives fair treatment, uses and has access to essential social services such as education and child and maternal healthcare [4,8-10]. For these reasons social capital is considered particularly relevant in the context of socioeconomic inequality and weak institutions [3,10], as well as in settings where collective ownership and non-state groups play an important role in the organisation of society [7,12-14].

The current study examines social capital among young women in Angola, a subject that has hitherto received negligible scholarly attention. The study focuses on young women as a priority group for two key reasons. Firstly, Angola's demographic profile, in which the majority of the population are under 25 years of age [15], necessitates a focus on this segment of the population. Secondly, the central role that young women play in their own and their family's well-being, alongside the risks that they face due to high levels of unwanted teenage pregnancy, child marriage and maternal mortality [16-18], emphasises the urgent need for knowledge that underpins feasible health promotion interventions to support this group [19,20].

Social capital: a conceptual overview

Social capital comprises sets of relationships or contacts that include mutually beneficial collaborations, trust and solidarity [21]. The basic idea is that our social environment is central to how our lives shape and the choices we make. The concept of social capital was formulated to scientifically examine how this interdependence with the social environment becomes an asset, i.e., a capital.

The social capital concept has been used in social science research for over a century, but

sociologist Pierre Bourdieu's work on understanding what resources matter for the reproduction of

power and privilege has been particularly significant [22]. He concluded that whereas monetary

capital is essential, social and cultural resources also create value and are important to the

individual's position in the social matrix [23]. Cultural capital comprises formal education,

specialised knowledge and cultural objects, which become resources when translated into beneficial

and socially valued behaviours. Social capital, on the other hand, comprises mutually recognised

relationships. Its value lies in the fact that individuals benefit through connections with other people

and their knowledge, skills, and material resources [23]. Thus, the quality and density of

relationships and the amount and type of resources within a network are crucial factors in

determining the value of social capital to different individuals [5,24].

Consequently, empirical studies of social capital encompass both actual social networks (so-called

structural social capital) and individuals' trust in that these networks will be a resource for fulfilling

needs and achieving goals (so-called cognitive social capital), [21]. There is an underlying

assumption of a reciprocal dynamic between these areas, which presupposes that those involved in

the network believe, feel and experience that caring for each other is part of their shared social

contract [24,25]. Thus, interpersonal solidarity and community peacefulness are understood as

reflecting existing social capital (so-called applied or operationalised social capital), [21].

Another critical conceptual distinction is between different social spheres. Social capital is

understood to create bonds between particularised individuals or groups known to each other and at

the same hierarchical level. In addition, social capital is part of more general social dynamics that

create trustful bridges between groups at different social levels that diverge with respect to formal

power [5,12]. Relationships and networks exhibiting different degrees of proximity to the

individual, such as family and neighbours, people in general, and representatives of formal

institutions, are considered to generate distinct types of social capital; the latter is what should

vertically link the desires of the public and the state [7,10,25].

Links between social capital and other contextual dynamics

There is consensus among social capital researchers that formal and informal networks, their extent

and what they provide to the individual, and the degree to which the individual perceives that

trusting and solidary relationships characterise their environment are key aspects of social capital

[1,3,21]. However, there is still a need for empirically based reflections on how the meaning of such

social phenomena fluctuate with time, place and other living conditions. In line with Bourdieu's

insight that social capital contributes to the reproduction of existing socioeconomic hierarchies,

scholars emphasise that the functioning of social resources cannot be separated from norms,

common sense assumptions, and the distribution of material resources and power relationships [26-

28]. Empirical studies have shown that social networks, as well as being a resource, can have

limiting effects on already marginalised groups, such as women in low-income countries [29-33]. In

addition, simplistic assumptions about trust, a factor sometimes used as the sole and most important

indicator of social capital, are challenged by studies showing that expressions of trust vary

depending on cultural norms as well as experiences of oppression and violence [27,29,34-35].

A recurring theme in these discussions is in what way the global north-based theories about social

capital are universal and/or generalisable and whether social capital policy and research have

sufficiently appreciated the distinct living conditions of different population groups. With this

background, contemporary social capital researchers point to the need for empirical studies that

include hitherto underrepresented regions and groups, noting that despite the contributions of some

recent thought-provoking studies, relatively few studies discuss social capital in the global southern

context [1-4].

Challenges and facilitators for the creation of social capital in Angola

Angola provides a particularly interesting case for broadening the empirical basis of these discussions. To understand social coexistence in Angola, it is necessary to consider the impact of colonial rule and civil war on society's organisation, demography and interpersonal relations [36-41]. For example, historical research indicates that the conditions for the creation of trust and solidarity were actively undermined in the colonial days by pitting communities against each other through the partitioning of agrarian land, the recruitment of some village elders for the slave trade, and the forced displacement of people for indentured labour in the later colonial years [37,87]. This weakening of social bonds reportedly continued during the civil war through so-called dirty warfare, that is, acts of war aimed at instilling fear and mistrust within and between societies [42,43]. The distrust-creating processes that started with colonialism continued after independence until the end of the war, just over 20 years ago. Hence, it is difficult to identify any historical period that can be characterised by peaceful and trusting coexistence, which promotes the development of social capital.

Research on contemporary Angola suggests that the social networking among today's youth is taking place in an environment of widespread poverty and poorly developed public services and infrastructure [44,45], limiting people's mobility and social interactions. Furthermore, urbanisation research describes social organisation in Angola as limited. It refers to irregular waves of internal migration (due to civil war and rural poverty) of people with different linguistic and regional backgrounds, creating unusually heterogeneous urban neighbourhoods [46,47]. It is argued that this, together with the authoritarian political governance has an inhibiting effect on social cohesion [48]. Other research has emphasised that community participation and organising are limited because of the continuous political and legal control of civil society organisations (CSOs), [49-52]. Harassment by security police and the detention of political opponents and human rights activists is said to have

created a "culture of fear" [53], echoing findings from social capital research on societies where

creating distrustful relationships was a conscious political strategy [25].

Angola is one of the world's most unequal countries, both in terms of monetary assets and gender

rights [55,56], which in other contexts have been shown to create social divides and have negative

effects on health, safety and trust between people [7,57-59]. Previous research and official statistics

reinforce the importance of studying the situation of young women in particular because they

clearly illustrate how gender inequality affects everything from everyday situations where women

try to protect their well-being to the extent to which governments take responsibility for meeting the

health needs and rights of women [8,60-62]. In Angola, women seem to fare worse than men in all

areas of life associated with systemic health inequalities, such as education, employment

opportunities, and access to essential healthcare [16,63,64].

However, in parallel with dynamics counterproductive to the development of socially supportive

environments for young women, examples of the opposite also exist. For example, family and

kinship networks are portrayed as the backbone of Angolan society, from which the individual

should be able to draw emotional, social and financial support [65-67]. These are even described as

dominating politics and the country's economic systems, especially the informal economic sector,

in which mainly women make their living [68,69]. Moreover, many Angolan churches have made

efforts since colonial times to provide social services, such as healthcare and education, in addition

to offering a kind of social insurance system [70].

There are also a growing number of CSOs focusing on women's rights, primarily in Luanda, and

their numbers have increased in recent years despite the political control mentioned above [53]. The

ondjango council culture, symbolising the rural tradition of collective solidarity, is used as a

metaphor for inspiring equality and strengthening women's rights because it includes norms of

mutual empowerment and concern for each other's welfare [53]. However, in practice, this tradition

is said to be challenged by postwar returnees with weak ties to the traditional norms of rural

reciprocity, political practices and youth culture that encourage individualism [71-73]. Finally, in

terms of non-organisational networking opportunities, internet-based social platforms offer meeting

places for young people; however, thus far, access to the internet is limited outside the capital [74].

Objectives

Social support systems play a crucial role in promoting young women's well-being and the

fulfilment of their human rights, not least in contexts where institutions are weak and socio-

economic and gender inequalities prevail. The present study contributes to this under-researched yet

significant field by exploring young Angolan women's access to social capital and how it is

clustered and associated with other life conditions. The study aimed to: (1) increase knowledge

about how young women in different parts of Angola describe and experience access to social

capital; and (2) capture how these social capital factors relate to young women's characteristics,

different living conditions and the context in which they live.

Materials and methods

This study used a subset of data originating from a larger research project named SADIMA (an

abbreviation of the Portuguese Saúde e Direitos das Mulheres em Angola), which investigates

social determinants of young Angolan women's Sexual and Reproductive Health and Rights

(SRHR) with both qualitative and quantitative approaches. The subset for the current study consists

of those women who answered at least one of the social capital questions (S1 Fig).

Study design

This was a cross-sectional survey-based study.

Setting

Angola gained independence from Portuguese colonisation in 1975. However, armed conflict over the country's natural resources lasted until 2002 [75]. Angola has 18 provinces with a population of approximately 35 million people, 70% of whom live in urbanised areas [55,76]. Rich in natural resources such as gems, minerals and oil, half of its people (49.9%) live in extreme poverty. Only 40% of the population has access to essential health services, and one-fifth is covered by social insurance. Among young people aged 15 to 24, the literacy rate is 80.7% for women and 85.9% for men [55,76].

For this study, three provinces—Luanda, Huambo and Lunda Sul—were purposely selected to capture the variation in living conditions in the country. These provinces differ in their colonial and war histories, Gini indices, fertility rates, education levels, employment opportunities, and health system coverage [16]. Huambo and Lunda Sul are rural provinces with land suitable for agriculture, but while Huambo is known for its strong agricultural tradition, the economy of Lunda Sul is mainly dependent on diamond prospecting. In Lunda Sul, the needs of the diamond industry have been prioritised since colonial times. The province lacks general investment in basic infrastructure and social institutions and has the highest urban poverty rate in the country [77,78]. Although Huambo also has a large poor population and the province needs major investment in infrastructure, there are signs of postwar recovery, such as the expansion of the road network and newly built suburbs [79]. Local cultural expressions continue to have a significant influence on daily lives in both provinces, with the succession of the Bailundo kingdom in Huambo and the Chokwe and Lunda cultures in Lunda Sul [80].

Outside the capital Luanda, the Luanda province is similar to other parts of the country, with large distances between smaller settlements connected by poorly maintained roads. However, whereas the city centres of the provincial capitals of Saurimo (Lunda Sul) and Huambo City (Huambo) have remained largely unchanged since colonial times, Luanda City has evolved into a hypermodern

metropolis with newly built, extravagant skyscrapers [39,81]. Luanda City, a centre of international

affairs, is home to more than 8 million people; Saurimo and Huambo City have 0.45 and 0.6 million

inhabitants, respectively. Although the capital has the lowest incidence of poverty in the country, it

has the largest number of poor people due to its high population density. Socioeconomic

inequalities are particularly evident on the outskirts of the city, where most of the poor population,

often migrants from war-torn and underserved provinces, live in humble dwellings squeezed

between gated communities [46,51].

Participants, recruitment and data collection

The SADIMA project targeted all women aged 18–24 years living in one of the selected areas at the

time of data collection. As no up-to-date household data was available, the sampling was done in

three steps, the objective being to ensure variation in terms of socio-economic status and urbanity.

In addition to the choice of provinces, six communes per province were selected on the basis of an

index constructed using principal component analysis (PCA) of five socio-economic indicators

relevant to both rural and urban areas (the indicators were: percentage of 15-24 years olds that could

read and write, population ≥5 years who used communication technology in the last 12 months,

households with proper roofing, households with proper sanitation, households with access to

suitable drinking water), [82]. Due to distance and impassable roads, two communes in Lunda Sul

and one in Huambo were replaced by communes with corresponding PCA values.

In the second step, when selecting urban and rural areas, different strategies were used. These

strategies were chosen because of a lack of up-to-date household data and inconsistent information

regarding permanent residents, which made it impossible to generate a random sample of

households within the communes. For the urban communes, data collection sites were chosen by

random selection of blocks using a grid [83]; for the rural communes, the main village (50 per cent

of the participants) and another randomly selected village (the remaining 50 per cent) were chosen.

In the third step, the interviewers started at a randomly selected location within the data collection

site and, using the spin-the-bottle principle [84], went in different directions from house to house

informing about the study, offering participation (if the household included someone eligible) and

conducting interviews until the specified number of interviews was completed (an average of four

interviews per day per interviewer).

The data collection was conducted between 1st of February 19th of May 2022. In Huambo and

Lunda Sul, the research team collaborated with local CSOs to establish regulatory acceptance for

the study to take place and identify suitable data collectors (S2 Table). Information about the study

was circulated at each study site one to three days before the data collection day to ensure

maximum outreach to eligible women. In urban areas, information leaflets were displayed on

bulletin boards and at building entrances. In addition, the community administrators or village

leaders in urban and rural areas were informed about the focus of the study and the day the research

team visited.

Trained, young university-educated women conducted the interviews to create a trusting

atmosphere. Snacks and drinks were offered during the hour-long interviews to avoid participant

fatigue. After the data collection, the rural participants were given 1 kg of salt and 1 kg of rice to

compensate for lost work time. With limited means of communication and extensive distances, the

risk of others being attracted to participate after hearing about the compensation was judged to be

minimal.

At the end of each day, the completed surveys were transferred to a Microsoft Excel worksheet

without any individual ID information and saved on a secure hard drive. During data collection,

controls were performed daily for internal consistency and after each team's first workweek for

interviewer bias.

The absence of reliable household data prevented the determination of the number of eligible

women who were not included in the study. However, information about the eligibility of the

household and whether the household participated in the study were recorded: 95% of eligible

individuals who were approached participated.

Ethics approval and considerations

Ethical approval was obtained from the Ethics Committee Institutional Review Board of the

Angolan Ministry of Health (24/C.E.). U/2021, 2021-07-07), the Ethics Committee at the

Universidade Católica de Angola (Approvação 153, CEIH 230, 2021-06-30) and the Swedish Ethics

Review Authority (Dnr 2022-06393-01, 2023-01-25).

Verbal informed consent was obtained using the DHS model [85]. Each question included an option

to decline to answer ensuring continuous voluntary participation. Ethical considerations

characterised all steps of the research process, including the development of the questionnaire, the

implementation of data collection, analysis and interpretation of data.

Data collection instrument

The SADIMA questionnaire was developed between July and December 2021 based on literature

searches and key informant interviews with ten public health experts and nine CSOs in the three

provinces. The first draft was assessed for appropriateness and understandability in focus group

discussions with five female students in Luanda and ten data collectors in Huambo. The paper and

Tablet versions were then tested in interviews with 66 members of the target population in Huambo.

The development of the questionnaire continued until the questions were perceived as logical and

ethical (sensitive questions towards the end), and the wording was precise, understandable and

respectful. To improve comprehensibility, common idiomatic expressions were added in

parentheses, and keywords in the two local languages of Umbundu (Huambo) and Chokwe (Lunda

Sul) were recorded on a separate sheet. The final version of the questionnaire was prepared using

Adobe InDesign for use on Tablets or paper, the latter only to be used in case of technical problems.

The SADIMA questionnaire consists of 150 questions in five sections. Section one asks about the respondents' general living conditions. Section two focuses on psychological well-being, and section three asks about gender norms. The fourth and main section covers the SRHR thematic areas of pregnancy and childbirth, family planning, and domestic violence. The survey ends with a section on social capital.

Study size

The initial estimated sample size of 754 young women, calculated based on the latest Angolan DHS report of women aged 15–19 years [16], was further adjusted for an expected response rate of 80% and a design effect of 2, resulting in a target of at least 1,885 young women to be recruited. This number was distributed across the included provinces proportional to the cubic root of the population size of selected communes [82].

Variables

From the SADIMA questionnaire, 21 questions related to social capital and 25 related to living conditions were included in this study. S3 Table describes the original instruments used to derive the survey questions and response alternatives, and how the related variables were created.

All *social capital variables* were derived from Grootaert' s extensive instrument [21], which was constructed specifically for developing countries, is theoretically well-founded, and is a key reference in developing newer and narrower variants [19,86]. Following recommendations from Grootaert et al., survey questions considered relevant to the context and provided sufficient information about theoretically defined areas were selected (structural social capital n = 10; cognitive social capital n = 6; operationalised and applied social capital n = 3). Three questions were adapted for context relevance (type of formal groups; type of benefits from formal groups; type of people to trust). For politically sensitive reasons, questions about trust in government officials were reformulated into one multiple-choice question.

As for the *general living condition variables* the Angola DHS 2014 questionnaire [85] was the

source of all questions except for those on food insecurity [87] and IPV [88]. Formal education,

literate, work, pregnancy, relationship status, intimate partner violence (IPV), household night

hunger, household wealth, province and type of residential area were included. The variables

literacy (Yes/No) and household wealth (quintiles) were included in the advanced analysis (reported

in Table 3 and S6 Table) to capture the theoretical literature's emphasis on the interaction between

cultural, financial and social capital [23]. Furthermore, the variables of work (Yes, permanent/Yes,

temporary work/No) and pregnancy (Never/ Yes, ≥18 first pregnancy/Yes, <18 first pregnancy)

were considered relevant to the respondents' networking opportunities and hence were also

included in the advanced analysis [29,89].

309 Statistical methods

The analyses were performed in five steps. First, the participants' general characteristics and

responses to social capital questions were summarised as the number and proportion per province

and type of residential area.

Second, exploratory factor analysis was applied to 17 constructed social capital variables to identify

underlying social capital factors using principal axes factoring with promax rotation based on

polychoric/tetrachoric correlations. The analysis was performed on complete data. Three possible

numbers of factors (4, 5, or 6), of which Kaiser's criterion suggested one, were investigated. The

final choice was guided by balancing the theoretical underpinnings and interpretability while

explaining the proportion of the variance (especially the change when adding further factors). The

stability of the final factor solution was examined with data stratified by province. The social capital

factors that were identified, were evaluated as the sum score of the included variables and further

dichotomised (high; low). Third, pairwise correlations between the dichotomised social capital

factors were evaluated and stratified by province and type of residential area. Tetrachoric

correlations with 95% bootstrap confidence intervals (500 iterations) were calculated, and the

correlation, if 0 was not included in the interval, was considered to be statistically significant. No

adjustment for multiple testing was performed.

Fourth, the distribution of the dichotomised social capital factors was summarised as the number

and proportion per province and type of residential area. Fifth, the associations between the four

selected participant characteristics and the five factors of social capital were modelled using logistic

regression. These are presented as odds ratios with 95% confidence intervals. Crude odds ratios and

odds ratios with mutual adjustment for the selected participant characteristics were calculated for

one social capital factor at a time. The analysis was stratified by province and by type of residential

area. Stratifying by province (type of area) is equivalent in this case to fitting a model for all data

with province (type of area) and interactions between province (type of area) and the participant

characteristic variables as additional terms in the model. This complex model was used to test

general associations between the participant characteristic variables and the social capital factors as

well as tests for homogeneity of these associations (i.e., presence of any interactions). The statistical

significance of the associations was assessed using likelihood ratio tests without adjusting for

multiple testing. We used a 5% significance level.

The analyses were performed using SPSS (version 29.0.0.0), R (version 4.3.2), package psych

(version 2.3.3), [90] (Revelle 2023) and rms (version 6.7-1), [91].

341 **Results**

342 **Participants**

343 A total of 2,109 women met the inclusion criteria and consented to participate in the study. Of

344 these, five lacked information on age and were excluded. The 34 respondents who had not answered

345 any of the social capital questions were also excluded, leaving a total of 2,071 respondents

346 considered for further analysis (S1 Fig).

Characteristics of the study participants

Table 1 presents the characteristics of those women overall and stratified by province and type of residential area.

350   **Table 1**. Characteristics of the study population stratified by province and type of residential area.

It shows a pattern of individuals from Luanda being in better life situations, those from Lunda Sul

in the worst life situations, and those from Huambo often being in between. For instance, 85.7% of

the Luanda participants, 53.8% in Huambo, and 41.4% in Lunda Sul were literate. Additionally,

material assets varied across the provinces, with 73% of the women from Luanda belonging to the

two upper household wealth quintiles, compared to 20.6% from Huambo and 6.2% from Lunda Sul.

Conversely, reports of household members going to bed hungry in the last four weeks increased

from Luanda to Huambo and Lunda Sul (28.2, 49.4, and 59.3%, respectively). For its part,

experiences of IPV varied from 37.4% among women in Luanda to 43.5 in Huambo and 66.5% in

Lunda Sul.

Similar variations were observed when comparing types of residential areas, to the detriment of

those living in rural and semiurban areas. Illiteracy was nearly five times more common in rural

areas than in urban areas, and household night hunger was reported more than twice as often by

rural participants than by urban participants. Participants from semiurban areas fell in between.

Regarding pregnancy history, 15.2% of the participants in urban areas reported a first pregnancy

before turning 18 years, compared with 33.9% in semiurban areas and 54.9% in rural areas. For

household wealth, 81.6% of urban participants were situated in the two upper quintiles, compared to

34.9% of semiurban participants and 1.7% of rural participants.

Participants' social capital by province and type of residential area

Table 2 presents the results for the social capital variables, ordered according to the type of social

capital they relate to: structural, cognitive, and operationalised and applied.

Table 2. Responses to social capital questions stratified by province and type of residential area.

* Percentage of participants with household group membership (Luanda n = 777; Huambo n = 576; Lunda Sul 254;
Urban n = 679; Semiurban n = 363; Rural n = 791)

Only 20% in total answered that their households did not belong to any formal group (cultural,

political, religious etcetera). Among women who reported household group membership, nearly all

(91.1%) reported membership in a religious group, and 79.0% indicated that this group was the

most important for their household. Education or healthcare were the most reported benefits from

such group membership (46.4% and 40.6%, respectively).

The responses regarding group membership varied considerably between the provinces (13.8, 14.5

and 46.9% in Luanda, Huambo and Lunda Sul, respectively). Similar patterns were observed for the

questions about supportive informal networks. The women in Luanda and Huambo more often

reported having access to financial or emergency support than did those from Lunda Sul (79.3 and

77.7% in Luanda; 74.5 and 69.6 in Huambo; and 55.5 and 59.3 in Lunda Sul).

Few of the study participants expressed trust in people in general (18.2%) or in people in the

community (14.1%). Minimal trust was expressed for government officials (4.0%) and traditional

midwives and healers (2.8%). However, when asked to choose the categories of people whom they

trusted the most, almost nine in ten (89.1%) indicated family and friends, whereas approximately

half stated that they only trusted family and friends (results not shown), even though they were

asked to identify three categories.

Compared to structural social capital, a reverse pattern was observed for cognitive social capital:

Overall, few respondents expressed trust in others, but in Lunda Sul and in rural areas, twice as

many respondents (about 20%) did so compared to the other residential areas. The exceptions were

trust in healthcare workers and CSO representatives, which reached 34.1 and 26.0%, respectively in

Huambo but were lower in the other two provinces (20.0 and 2.1% in Lunda Sul; 9.0 and 6.6% in

Luanda). In addition, few indicated trust for teachers and police/military (13.6 and 13.6 in Huambo;

12.8 and 1.4 in Lunda Sul; 6.0 and 4.3% in Luanda).

When asked about conflicts, 'economy and wealth' and 'educational level and work success' were

most often mentioned as causes of conflicts among the total study population (51.5 and 44.1%,

respectively). The women in Huambo stood out with many reporting conflicts over land ownership

(67.8, 33.7 and 30.5% in Huambo, Luanda and Lunda Sul, respectively), while basic natural

resources such as water was more commonly stated as a source of conflicts by those in Lunda Sul

and Luanda (41.6, 40.1 and 26.0% in Lunda Sul, Luanda and Huambo, respectively).

Exploratory factor analysis of social capital variables

The exploratory factor analysis identified five social capital factors. Based on complete cases (n =

1930) of the 17 social capital variables, the first analysis explored 4-, 5- and 6-factor solutions and

identified institutional trust and economic trust as poorly explained by the underlying factors. In the

6-factor solution, institutional trust was assigned a separate factor, while the uniqueness of

economic trust was 0.9 or greater in all cases. It was decided to keep institutional trust as a factor on

its own and rerun the factor analysis without institutional trust and economic trust. The second

analysis was based on complete cases (n = 1945) with a satisfactory Kaiser–Meyer–Olkin measure

of factor adequacy of 0.74. A 4-factor model explaining 45% of the variance was retained: 1) group

membership, 2) informal network, 3) interpersonal trust, and 4) solidarity interaction (see Figure 1,

showing factor loadings larger than 0.25 in absolute value and correlations between the variables).

Besides interpretability, the retention of 4 factors was supported by Kaiser's criterion. For

comparison, a 5-factor solution suggested splitting the solidarity interaction factor in two, but the

additional granularity was not considered to be worth the 4% increase (49% vs 45%) in the

explained variance. The four identified factors were satisfactorily recovered when the data were

analysed for each province separately (Figure 1). With institutional trust, the analysis thus arrived at

five social capital factors. These five factors have consistently been analysed separately.

The proceeding correlation analysis revealed that the identified factors varied in correlation patterns

(see S4 Table). The two structural factors correlated with each other in all study groups, but none of

these factors correlated with interpersonal trust or solidarity interaction. However, they correlated

with the institutional trust factor but only in some study groups (group membership in all study

groups except for Lunda Sul; informal network in the Huambo, semiurban and rural study groups).

The institutional trust factor was also correlated with solidarity interaction, but only in the Huambo

and rural study groups. Finally, the interpersonal trust factor correlated only with solidarity

interaction but only in the Lunda Sul, semiurban and rural groups.

429   Social capital factors across provinces and area types

The polar graph in Figure 2 displays the proportion of the respective study group ranking high on

the dichotomised social capital factors (see S5 Table for detailed results). It shows that the

differences between the study groups were greater when the study population was stratified by

province than when it was stratified by type of residential area. A lower percentage of women in

Lunda Sul (approximately 40%) than in all remaining study groups (approximately 60%) ranked

high in terms of group membership and informal networks.

A different pattern was observed for the two cognitive factors; proportionally, more women in

Lunda Sul and the rural areas ranked high in terms of interpersonal trust (48.6 and 45.1%,

respectively, compared to 27.1-34.1% in the other study groups), while more women in Huambo

did so in terms of institutional trust (46.2% compared to 14.8-40.1% in the other study groups).

Regarding social capital related to ambient solidarity interaction, women in semi-urban areas stood

out as the least advantaged (80.8, 72.4 and 61.8% in urban, rural and semi-urban areas

respectively). The results for this applied factor were closer to the structural than the cognitive

factors.

Associations between social capital and other living conditions

445   Table 3 presents the associations that proved significant after adjustment, with regard to the

446   association analysis between each of the living condition variables and the social capital factors per

447   province and type of residential area (see S6 Table the detailed results).

448 **Table 3**. Simplified overview of associations between the dichotomised social capital factors and
449 the selected participant characteristics based on multivariable logistic regressions.

Institutional trust													
Solidarity interaction													

It demonstrates that when an association existed with favourable living conditions, it was positive for structural social capital factors and almost always negative for the cognitive ones. Thus, women with a generally better life situation were more likely to have supportive group and network connections, but they tended to trust other people to a lesser extent than the less fortunate. The informal network factor was most strongly associated with the other living conditions, while the solidarity interaction factor was seldom associated with these conditions.

Literacy is an example of this pattern. For urban women, being literate doubled the odds of benefitting from favourable group membership (OR = 2.06, 95% CI = 1.27-3.34) or informal networks (OR = 1.97, 95% CI = 1.17-3.30), while it almost halved the odds of having high interpersonal trust (OR = 0.58, 95% CI = 0.36-0.95). Similarly, for rural women, being literate raised the odds of ranking high on the informal network factor (OR = 1.53, 95% CI = 1.12-2.09), while it halved the odds for high interpersonal trust (OR = 0.50, 95% CI = 0.37-0.68).

Household wealth was primarily associated with strong informal networks among women outside the capital. This was most obvious among women from semiurban areas where wealthier individuals had three to four times greater odds of having elevated informal network levels (OR = 4.68, 95% CI = 2.48-8.82; OR = 2.90, 95% CI = 1.71-4.92 for the 4-5th and 3rd quintiles, respectively). This association was also found, albeit less strongly, for the wealthiest quintiles in

Luanda (OR = 2.83, 95% CI = 1.59-5.05) and Huambo (OR = 2.05, 95% CI = 1.18-3.57) and the

intermediary wealth group in Lunda Sul (OR = 1.83, 95% CI = 1.09-3.09). The only association

between household wealth and group membership was found for the intermediary wealthy rural

category where odds more than doubled (OR = 2.28, 95% CI = 1.27-4.11).

As for the associations between the women's work situation and their structural social capital, it

was, above all, a permanent job that made a difference but only for women in the Huambo and

Lunda Sul provinces. Having a permanent job substantially increased the odds of benefitting from

group membership (OR = 2.42, 95% CI = 1.38-4.24; OR = 3.98, 95% CI = 1.61-9.84, respectively)

in these rural provinces. Having a permanent job was also positively associated with a high rank on

informal networks for semiurban, rural and Huambo women (OR = 4.02, 95% CI = 1.78-9.10; OR =

2.94, 95% CI = 1.72-5.01; OR = 2.77, 95% CI = 1.61-4.77, respectively). Additionally, having a

temporary job doubled the odds for rural women to rank high on group membership (OR = 2.03,

95% CI = 1.38-2.98) or informal networks (OR = 2.01, 95% CI = 1.38-2.92).

Finally, the women's pregnancy history was the living condition with the fewest associations with

social capital. A positive association with informal networks was found in the three following

instances: for women in Luanda and urban areas who had never been pregnant (OR = 1.78, 95% CI

= 1.11-2.85; OR = 1.87, 95% CI = 1.10-3.21, respectively), and for those in semiurban areas who

had their first pregnancy after the age of 18 (OR = 1.92, 95% CI = 1.14-3.23).

Discussion

Key results

This study investigates, to date, an under-researched population of young women in a postwar

setting with striking socioeconomic and gender inequalities. A comprehensive approach,

incorporating a vast range of social capital domains proposed in the literature, was adopted to

investigate how social capital materialises among them. The one-by-one description of the social

capital variables showed, all respondents aggregated, that more participants had experienced

beneficial networks and solidarity between people than had trust in people outside the family and

friends' circle. The variation in access to social capital was less pronounced than for literacy and

household wealth. This raises questions about whether women with the same amount of social

capital, but different access to material and educational resources, equally benefit from the social

capital resources they have.

The factor analysis of the social capital variables aligns with established social capital research.

Factor resolution could be achieved once economic trust and institutional trust were excluded. This

resolution showed that the first set of variables aggregated pertained to structural capital (group

membership and informal network), and the following variables pertained to cognitive

(interpersonal trust) and applied social capital (solidarity interaction). The institutional trust factor

was kept as an independent factor. These five factors mirrored the theory of the various aspects and

levels of social capital well.

As the literature suggests, the participants with better access to education, work and material

resources also ranked higher on structural social capital. However, this pattern did not hold for the

cognitive factors. Thus, even those young women who were more materially and educationally

advantaged scored low on trust, one of the social phenomena that has the potential to transform into

a health-promoting resource. This highlights the need to further investigate what social spheres

young women in differing circumstances find supportive.

The difference in social capital access was greater between the provinces than between the rural and

urban populations, suggesting the influence of macro factors, in addition to rurality. In line with

theories of reciprocal dynamics of combined resources, the participants in the poorest province

exhibited the lowest levels of structural social capital. Furthermore, the research revealed intricate

connections between social capital and the other tested living conditions. Whilst the research

indicated geographical variation in which living conditions increased the odds of having high social

capital, there was a consistency when associations proved significant. In these cases, the odds ratios

were often similar across the different groups of women.

Overall, the results suggest that multifaceted combinations of personal and societal dynamics

influence the formation and meaning of the different social capital factors. Thus, this study supports

previous research that underscores the importance of studying different social capital aspects

separately. Furthermore, it highlights the necessity of considering how social capital relates to other

resources and each locality's unique conditions when considering the integration of social capital-

enhancing initiatives as components of health and human rights promotion interventions.

Limitations

The study identified areas that require further research to understand better the relationships

between diverse groups of people, their roles for young women in different living areas, and what

trust represents. This highlights the complexity of social capital and the need to use multiple factors

that reflect social forces and spheres in the respective context.

The research team opted for an interview-based data collection rather than a self-administered one,

based on a sample that allowed for variability among the respondents that could reasonably mirror

that of the country. The high level of illiteracy in the study population and the broad geographical

dispersion in the country required a data collection procedure that could counterbalance the material

and practical limitations of a countrywide randomised sample.

Several measures were taken to create a comfortable and permissive interview environment; for

ethical reasons as well as to prevent desirability bias that may arise due to the potential power

imbalance between the interviewer and participant. To reduce the risk of misclassification, the data

collection instrument was thoroughly conceived and adapted to the local context. It covered a wide

variety of social capital aspects and other relevant constructs and aligned as closely as possible with

the theories and conceptual frameworks from which its different parts were derived.

Regarding the household wealth variable, it is worth noting that the overall distribution of wealth

obtained in the study group mirrors well the wealth distribution reported in the latest Angola DHS

(see S3 Table). However, due to the skewed distribution of wealth in the included provinces, there

was a loss of precision in the association analyses.

Interpretation

Angola's future development relies heavily on its young women, as they constitute a significant

portion of the population and play a critical role in maintaining their own and their family's well-

being. Their ability to receive support from relationships within the community and from

representatives of societal institutions is crucial. It is therefore important to increase knowledge

about young women's access to these social resources, especially in the context of an undersized

welfare system, and socioeconomic and gender inequality [3,4,9,12,13,20,4].

The study shows that social capital among young Angolan women is multifaceted and

heterogeneous. The associations between individual socioeconomic variables and any of the social

capital factors were far from uniform and manifested differently depending on where the women

lived (province or type of residential area). Regarding structural social capital, the study echoes the

claim that having access to supportive networks is linked to the possession of material and

educational resources [2,5,23,29,30]. It revealed that structural social capital and positive

experiences of solidarity interactions were most readily available to women residing in the capital

province, were better literacy and financial status were more common. Similarly, the study group

living in the poorest province, Lunda Sul, had the lowest access to structural capital and solidarity

interaction, its urbanised areas included. The study does not explain the reasons behind this but

recalls research suggesting that repeated social shocks and the struggle for survival could lower the

ability of rural communities to maintain a strong culture of collective bonds and lead to difficulties

in exercising interpersonal solidarity [27,34-36,50-52,83]. These results point towards a need to

research how various aspects and levels of poverty, area deprivation, historical and gender-based

dynamics impact the scope and nature of social capital [7,33].

Moreover, the study points to previous research showing that the value or usability of existing

social networks is conditional on the availability of other resources [5,23,26,30]: in this study,

structural social capital was more evenly distributed among participants than educational and

material resources were. Further research is therefore needed to clarify in which situations a social

network, backed only by limited material resources, can play a supportive role for young women in

this context. The complexity of this issue showed in the patterns of associations between social

capital and other living conditions. Literacy was, for example, the attribute most often found to be

positively associated with social capital, but the strength of associations with household wealth and

work situation were greater (higher odds ratio). Among other things, this casts doubt on the idea

that social capital could substitute for financial or other assets [14]. Instead, it indicates that the

functioning of social capital is intertwined with other assets and that its usability should be

evaluated in relation to these other assets and the specific situation in question.

Regarding the content and character of structural social capital, the study found that most women

were affiliated with a religious organisation. This ties in with previous research on the historical

role of churches providing education, healthcare, and social services in Angola [70], and shows that

they still play such a role. The study did not investigate how their support compared to that

provided by current governmental or nongovernmental actors, nor did it address whether any of

them supported women's rights. However, it showed that the participating women's trust in

institutional representatives, such as health workers, teachers, and CSO representatives (including

from churches), was consistently low. This is reminiscent of research pointing out the complexity of

group belonging, particularly for vulnerable individuals: even if a group provides certain types of

support, its positive role in other aspects of life is not self-evident [28,29,31,32,34]. In view of the

challenges reported by a considerable proportion of the participants, it is imperative to further

explore which network characteristics have the potential to promote health and in what respect.

About the nature of interpersonal trust and its applied factor of solidarity interaction, the results

connect to certain social capital research but challenge others. As is the case in our study, previous

research has shown that difficult living conditions may lead to low trust in others [5,34-36]. Trust

was consistently low but slightly higher among rural women than their urban counterparts, and

interpersonal trust only correlated with solidarity interaction in the study groups outside of Luanda.

This is consistent with social capital research pointing towards rural women's role in community

cohesion [7], as well as research on Angola claiming that the rural environment maintains a culture

of collective togetherness, while urban areas are characterised by social fragmentation

[42,47,71,73].

Conversely, the study's results emphasise the need for further research into the character and role of

the various spheres where social capital is generated, operationalised and applied. The participants

expressed greater trust in their family and friends compared to people in the neighbourhood or the

wider community, indicating that they viewed these social spheres as separate. This notion is further

supported by the fact that trust in the neighbourhood and the general community was considerably

lower than reports of perceived solidarity interaction. This implies that the latter – the applied

solidarity interaction factor – may have captured the young women's cognitive capital derived from

family and friends rather than the neighbourhood sphere. It is an example of how researching a

hitherto understudied group sheds new light on the dynamics of social capital, in this case, young

women who may have distinct reasons to place more trust in those within their immediate circle

than in those outside of it [20,53].

Methodology-wise, these results entail that the role of family, friends, neighbours, and community

members should be investigated separately and not, as is often the case [25,21], considered part of

the same category of particularised, known others in relation to which bonding social capital is

assumed to be created. Since previous research has shown that trust in this category is mostly

associated with health outcomes, it should be clarified who is perceived to belong to what unit, what

role the respective unit has and what contextual dynamics can influence such appraisals [1,5].

In Angola, as in many parts of the world, the concept of family extends well beyond the nuclear

family household, and the strength of familial bonds or friendship alliances can even surpass that of

the state [66,67,69,71]. Thus, the distinctive results regarding trust in family versus community and

institutional representatives also raises questions about how trust in random government officials or

institutional representatives should be understood. For example, to what extent it uniquely

represents a relationship with the state as a distinct entity. In this context. a more thorough attention

to the interaction between family and kinship networks, and informal and state institutions is

warranted; because it involves the very foundation on which social networks are established, their

composition, the definition of social spheres, and the connections between individuals and larger

society including the state [10,25,59,65].

The study showed that several living conditions were associated with social capital, and it is

therefore possible that social capital also influences young women's life opportunities. However,

further research is required to determine the meaning and importance of the various types of social

capital for young Angolan women's well-being. For instance, the manner in which the extent and

quality of social networks, in addition to trust in diverse social spheres, is linked to access to health

services or the protection of young women from various forms of gender-related vulnerability.

Generalisability

This study has identified areas for further research, which should be considered when generalising the findings to young women in Angola and elsewhere. In addition, in other parts of the country, there may be networking and trust aspects other than those seen in the included provinces. However, the respondents share many life circumstances with young women in other contexts were socioeconomic and gender inequality shape everyday life. Therefore, our results have the potential to provide insights into how social capital works for comparable populations.
