Abstract

Background: Adults with congenital heart disease (ACHD) frequently experience gaps in lifelong ACHD specialty care, leading to preventable complications, hospitalizations, and premature mortality. However, effective, scalable, accessible, and sustainable strategies to reduce these gaps are lacking. Digital health offers potential solutions but requires a rigorous scientific approach in its design to address the needs of the target population.

Objective: To describe the development of a theory-based, community co-designed digital health intervention to improve lifelong ACHD care.

Methods: We integrated theory-based behavioral frameworks, semi-structured qualitative interviews with patients and clinicians, and a community-engaged approach to develop a digital health intervention for ACHD. The primary behavioral target was completing an ACHD specialist appointment. We conducted Capability, Opportunity, Motivation, and Behavior (COM-B)-guided semi-structured interviews with ACHD patients and clinicians to identify barriers to specialized care amenable to a digital intervention and patient-centered goals for the digital tool. The community partners helped develop key intervention objectives, create a theory-driven framework, and specify how each intervention component targets specific COM-B barriers.

Results: We interviewed 54 participants (37 ACHD patients and 17 clinicians) and engaged 21 community partners representing 4 advocacy organizations. Design objectives emphasized addressing patient loneliness, ensuring accessibility and credibility, and enabling scalability while centering patient perspectives. Participants identified four priorities: providing credible resources, uplifting patient voices, customizing to patient needs, and centering positivity and joy. The digital tool, named by community partners as Empower My Congenital Heart (EMCH), was designed within the web- and mobile-based, Apple- and Android-compatible, Eureka Digital Research platform (University of California, San Francisco). Key intervention components included educational modules, peer support, appointment planning nudges, and a digital medical passport. The EMCH's theory-driven framework specifies how each intervention component targets specific COM-B barriers to specialized ACHD care.

Conclusions: The theory-driven, community co-designed EMCH digital tool is a rapidly scalable approach to improve guideline-recommended specialized ACHD care. Future studies will evaluate the acceptability, feasibility, effectiveness, and implementation outcomes to provide insight into a novel tool to reduce preventable morbidity and mortality in ACHD.

Trial Registration: The National Clinical Trial number for this study is NCT06581484.

Keywords: Heart Defects, Congenital; Adult; Digital Health; Mobile Applications; Health Behavior; Patient-Centered Care; Community-Based Participatory Research; Implementation Science

Introduction

Adults with congenital heart disease (ACHD) are a rapidly growing population [1,2]. The American Heart Association and American College of Cardiology guidelines provide recommendations on the frequency and intervals at which ACHD patients should receive lifelong care from clinicians specialized in managing ACHD [3,4]. Despite this, up to 85% of ACHD patients experience gaps in receiving specialized care throughout their adult life [5-8]. Those with care gaps are at a higher risk of poor outcomes, including emergent admissions, need for urgent cardiac procedures, and mortality [9-11]. Thus, there is a need to identify accessible, scalable, and sustainable strategies to reduce the care gaps and improve outcomes for ACHD patients.

Individual-, provider-, and system-level barriers contribute to gaps in lifelong ACHD care [5,12,13]. Interventions, such as education and support for navigating the health system, can reduce gaps [14-16]. However, existing interventions are clinic-based (nurse-led education, transition clinics); limited to single-center studies of 16-21-year-olds focused on transfer from pediatric to ACHD care; and are resource-intensive, inconsistently implemented, and constrained by reimbursement, clinic time, and missed visits [17-19]. Effective and scalable strategies to support all adults (≥18 years), including those who did not transfer from pediatrics or were later lost from care, to both establish and maintain life-long specialized ACHD care remain unknown. Web- and mobile-based solutions offer a scalable way to overcome these barriers by engaging patients outside of clinic visits [20,21]. Although 94% of ACHD patients use smartphones and most report openness to app-based solutions [22], these tools have not yet been developed to promote lifelong specialized ACHD care.

App-based interventions to improve guideline-adherent care need to be grounded in evidence-based theoretical frameworks [21,23]. This results in interventions being more robust, adaptable, and effective in achieving lasting behavior change in real-world settings, not just in ideal research environments [24,25]. Also, designing interventions to change behaviors requires an understanding of the perspective and psychosocial context of the people who will use them - a concept fundamental to community-engaged research [26-28]. Combining theory- and community-driven approaches is vital to ensure that interventions are usable, acceptable, and move beyond *what* works to *how* to make it work in diverse, complex environments [25,29]. To our knowledge, no existing ACHD interventions, digital or otherwise, have employed this combined theory- and community-driven approach.

Thus, the aim of this paper is to describe a theory- and community-driven approach to designing a digital health intervention to promote lifelong ACHD specialist care. The methods and findings can inform others developing interventions to improve care for ACHD and other chronic lifelong conditions.

Methods

Overview of the intervention development process. We began by establishing guiding principles for intervention design (**Table 1**). We then integrated behavioral frameworks with semi-structured interviews and community-engaged research to identify and refine intervention components for promoting lifelong specialized ACHD care (**Figure 1**).

Table 1. Guiding Philosophy for the Design of an ACHD Digital Health Intervention
Characteristics designed to drive evidence-based approach
· Explicitly evidence-based, using scientific rationale for behavioral theories
· Expert guidance for content creation (e.g., ACHD follow-up guidelines)
· Person- and theory-informed approach at all stages of design and evaluation to meet individual needs of the target ACHD population
· Non-commercial, developed by the named team of medical and behavior change experts
Characteristics designed to encourage uptake and long-term engagement
· Nimble, user-friendly interface with lay-person oriented messaging, leveraging existing tested capabilities and proven methods of the digital research platform
· Simplicity, with direct, concise, and actionable messaging designed to foster participants' capabilities, opportunities, and motivation
· Proactive, repetitive content delivery using nudge principles rather than relying on patients to seek out information, enhancing its reach and impact
· Mechanisms for modeling and sharing experiences within the user community, aimed at boosting self-efficacy and promoting positive affect among participants

Behavioral frameworks: We selected evidence-based behavioral frameworks to guide intervention development. The study team chose 4 primary frameworks as they complemented the needed areas to design the digital tool. First, the Behavior Change Wheel (BCW) theoretical model was primarily used to provide a rational, evidence-informed approach to specify the target behavior, identify the barriers and enablers of the behavior, and select the means by which intervention can change behaviors [30,31]. To make the intervention equitable and relevant to diverse ACHD patients, we incorporated the principles of digital health equity, diffusion of innovation, and behavioral economics in its design and adoption (**Table 2**) [32-34].

Table 2. Theoretical frameworks for designing ACHD digital intervention	
Frameworks	**Summary of the Theoretical Frameworks**
Behavioral Change Wheel (BCW) [30]	**1.** Define health problem in behavioral terms (e.g., scheduling and completing timely ACHD specialist visit) **2.** Understand determinants of behavior (Capability, Opportunity, Motivation for Behavior Change-COM-B Model) **3.** Link determinants of behavior to identify domains most likely to influence behavior **4.** Select intervention functions that are means by which an intervention changes behavior (i.e. education, enablement, persuasion, or training)
Digital Health Equity [32]	Apply concepts of: **1.** Health literacy: include relevant content: assume no background knowledge of participants, avoid cognitive burden from too much information and use simple numbers and percentages to develop content **2.** Readability: use plain and clear language tested with target population **3.** Ease of Use: accessible on various platforms, format conducive to comprehension; content appeals to users of different identities and backgrounds
Diffusion of Innovation [33]	Engaging all levels of adopters (highly engaged and less engaged CHD patients) and CHD champions in the design, adoption, and dissemination of the intervention
Behavioral Economics [34]	Nudges and default settings of the digital tool alter behavior and facilitate decision-making process.

The BCW framework is based on multiple models of health behavior and is designed to enable the systematic development of interventions. The BCW has been identified as an effective framework at changing individual health behavior in various cardiac and noncardiac chronic conditions but has not yet been used to promote lifelong ACHD care [35-40]. The core driver of behavior in BCW (or hub of the wheel) is the COM-B model, which consists of three necessary conditions for a given '**B**ehavior' to occur: (1) '**C**apability' (psychological/physical); (2) '**O**pportunity' (physical/social); and (3) '**M**otivation' (reflective/automatic). Exploration of a given behavior in relation to the COM-B components helped identify which psychological determinants need to be addressed to achieve behavior change. The BCW framework then supports the selection of intervention functions and policy categories. Intervention function refers to broad categories of ways an intervention can change a behavior. As applicable, one or more of the intervention functions can be chosen and applied depending on the COM-B component targeted for change. The nine intervention functions described in BCW include education, persuasion, incentivization, coercion, training, restrictions, environmental restructuring, modeling, and enablement. Policy categories comprise the final outer layer, or the wheel's rim, and help identify the types of policy categories one may wish to consider to further influence the drivers of behaviors (COM-B).

Semi-structured Interviews: The semi-structured interview for this study were part of a larger qualitative study that was conducted to identify barriers and enablers for lifelong specialized ACHD care, described in detail separately [12]. For this study, we used COM-B as a guide to identify barriers amenable to a digital intervention and the patient-centered goals for the digital tool. Briefly, we recruited ACHD patients (≥18 years) who spoke English or Spanish and could provide informed consent. Initially, patients were recruited from University of California San Francisco (UCSF) using chart review and purposefully sampled [41] to recruit those with >3-year gaps in ACHD specialist care during their adulthood. Once we achieved thematic saturation [42] at UCSF, we recruited non-UCSF patients with convenience [43] and snowball sampling [44] to have representation from all regions of the US (Northeast, Southeast, Midwest, Southwest, and West). All patients underwent an informed consent process and completed a demographic questionnaire at the end of their

interview. Clinicians included adult congenital cardiology and pediatric cardiology nurses, doctors, coordinators, board-certified patient advocates, and program leaders. Clinicians were recruited from UCSF and outside UCSF using a similar approach of snowballing, thematic saturation, and to have representation from all regions. Separate interview guides were developed for patients and clinicians using content domains within the COM-B framework and to explore opinions towards a digital tool and its key features (**Supplementary material**). Interviews were conducted over Zoom, each lasting 45-60 minutes, were audio-recorded and professionally transcribed.

Community-engaged approach: The goal of the research team in recruiting community advisory board (CAB) partners was to represent diverse perspectives in ACHD care. We primarily used convenience sampling to recruit patients from UCSF and snowball sampling to recruit patients outside UCSF, clinicians and advocacy representatives. We collaborated with the CAB partners to adapt the BCW components to identify ways to promote lifelong specialized care. CAB partners were involved in all aspects of intervention planning, design, and implementation, including reviewing findings from semi-structured interviews, drafting and finalizing tool features and branding, sharing personal experiences, and partnering throughout iterative prototype testing. They also assisted with recruitment of interview participants and contributed to implementation, evaluation, and dissemination activities. One patient partner (JV) led the creation of a design guide to ensure consistency and uniformity in materials, built the study website, and developed strategies to elevate participant experience. CAB members shared their stories as part of the intervention content and partnered as co-authors in scientific and community writing and dissemination. CAB members provided ongoing input through monthly hour-long meetings. Some CAB members also participated as test users in the pilot testing of the tool for iterative refinement. Meeting discussions were documented in study logs and analyzed by the research team to identify key themes and design recommendations. Community feedback was integrated iteratively with interview data to inform intervention components, branding, and content strategy.

Data Analysis: We conducted thematic analysis of all semi-structured interviews. Each transcript was coded independently by at least two coders to identify themes and subthemes related to barriers and facilitators to lifelong specialized care and towards key aspects of digital tool. The two versions of coded transcripts were then compared to resolve discrepancies between coders and to generate a single, final coded transcript for each interview. We created a structured data matrix using Rapid Qualitative Analysis [45], an action-oriented method for qualitative data analysis conducted in Microsoft Excel, to efficiently produce results for real-world interventions. Using the matrix, cross-participant comparisons were made to identify determinants of ACHD specialized care and identify factors associated with use of the digital tool. We summarized the matrix findings via iterative group meetings of five team members (AA, KM, KB, JM, PA), which were then reviewed by the CAB members. Through ongoing, iterative review of CAB meeting discussions documented in study logs, we informed, planned, and refined the intervention components concurrent with their development.

Ethics Approval: Ethical approval for this study was obtained from The University of California San Francisco Institutional Review Board (IRB # 22-36667). Verbal informed consent was obtained from interview participants for anonymized patient information to be published in this article. The National Clinical Trial number for this study is NCT06581484.

Results

Study population: We interviewed 54 participants (37 patients and 17 clinicians) to understand the determinants to lifelong ACHD specialized care and key features of the digital tool (**Table 3**).

Table 3: Characteristics of Study Participants		
Characteristic	**Patients (N=37)**	**Clinicians (N=17)**
Age, median (range)	32 (18-65)	NA
Female, n (%)	21 (57%)	-
Race/Ethnicity, n (%)		
- Asian	8 (21%)	-
- Black/ African American	6 (15%)	-
- Hispanic/ Latino	7 (18%)	-
- White	13 (35%)	-
- Other/Multiple	3 (8%)	-
Education ≤ some college, n (%)	14 (41%)	-
Care gap ≥3 years, n (%)	13 (35%)	-
Recruitment Source		
- UCSF	27 (73%)	9 (52%)
- Community/snowball	10 (27%)	8 (48%)
Clinician Roles		
- ACHD/Pediatric Cardiologists	-	8 (47%)
- Nurses/NPs	-	6 (35%)
- Other (coordinators, advocates)	-	3 (18%)

The CAB included 21 members comprising 11 patients or family members who are racially diverse and from all regions of the US, six pediatric or ACHD physicians, a social

worker, an ACHD nurse, two nurse practitioners, and six advocacy representatives, some of whom represent more than one role. Advocacy organizations included the Adult Congenital Heart Association (ACHA), Conquering CHD, The Mended Hearts, and Team Uncle Joe [46-49].

CHD-related unique challenges to inform ACHD digital intervention design and features: The qualitative interviews and our CAB partners identified challenges uniquely faced by ACHD patients. These challenges centered around users' perspectives, loneliness, feasibility, accessibly, credibility, and scalability (**Table 4**). They then helped identify design objectives and intervention features that could addresses these challenges. The interview participants also identified four patient-centered goals to consider during the design of the digital tool (**eTable 1**): i) Easy access to credible resources (How can we make it easier to connect patients with pre-existing resources); ii) Uplifting of patient voices (How can we uplift patient voices to create a personal connection); iii) Customization to patient needs (How can we cater to different needs within the community); and iv) Centering positivity and joy (How can we bring positivity and joy into our tool).

Table 4. Digital Tool Design Objectives and Features for ACHD Specialized Care			
Key Findings	**Design Objectives**	**Key Features**	**Data Source**
Perspectives: CHD patients might not understand the need to establish or maintain care with an ACHD specialist especially when they are otherwise feeling well. At times, they may prefer to avoid thinking about their heart to prevent their health condition from interfering with their life	An approach which promotes well-being, rather than illness management	Empowering tone—Focus on the patient as the hero of their journey, avoiding language that centers on illness or portrays them as passive recipients of care	Semi-structured interviews and CAB consensus
		Building motivation for changes from first user contacts and in recruitment materials	CAB consensus
		Begin with simple, concise interventions, such as clarifying basic terms like the distinction between defect and disease, while offering the option for users to explore more detailed resources	CAB consensus
		Allowing users to engage with intervention elements and information which are most relevant to them	Semi-structured interviews, confirmed by CAB
Loneliness: CHD patients often feel lonely in their health journey and don't know how their condition is similar or different compared to others	Build a community	Patient's narratives shared as "Peer Empowerment" quotes to provide practical guidance	CAB consensus
		Engage the users in sharing their experiences	CAB consensus
		Linking resources, including, community events, community building opportunities, or peer-to-peer connections	Semi-structured interviews and CAB consensus
Feasibility: Given the intervention's goal to target multiple barriers to the behaviors, there was a risk for the intervention to be too large and complex for the project team to satisfactorily develop it for the many unique needs that CHD patients have, especially within the resources available	Efficient and multiphase design	Phased development of the features with the initial phase targeting key drivers for gaps in ACHD care (e.g., knowledge about CHD care, symptom management, etc.)	CAB consensus
		Addressing barriers that can achieve multiple outcomes (e.g., patient activation and engagement which can improve timely ACHD visits, mood, and general illness perception)	CAB consensus
		Strike balance between making education and resources broadly applicable to CHD patients, while ensuring it is relevant and has impactful and useful information for users, while being cost-effective	CAB consensus
		Continuous Development—Regularly adapt and improve features based on user needs and feedback with the opportunity to modify existing content or create new content or features	Semi-structured interviews, confirmed by CAB
Accessibility: Most CHD patients are young and have other priorities	Enabling easy, timely, non-intrusive	Short, succinct, actionable information that users can benefit from in just a few minutes	CAB discussions guided by findings from semi-

	access to concise information, which can be read and acted on quickly when needed		structured interviews
		Mobile friendly—easy to read information that fits on a phone screen	Semi-structured interviews, confirmed by CAB
		Content delivered to patients using nudge approaches through email, short message service (SMS), or app notifications that act as gentle reminders	CAB consensus
		Contents delivered as small bursts of information over time	CAB consensus
		Automated delivery of the content, independent of whether users are seeking the information	CAB discussions guided by findings from semi-structured interviews
Credibility: There is an abundance of information, but it isn't reaching the CHD patients, it often seems overwhelming, and it's unclear which one is reliable	Use credible sources for content creation rather than re-inventing content that already exist.	Partnering with community organizations to curate exiting information	CAB discussions guided by findings from semi-structured interviews
		Formatting and delivering content in an easy to understand and readable way	Semi-structured interviews and CAB consensus
		Tailoring content based on repeated feedback from participants about their needs and priorities	CAB consensus
Scalability: There could be variations in terms of age, health literacy, prior engagement in care and research, making it difficult to tailor interventions to meet these diverse needs	Design and content tailored to diverse needs	Use web and mobile based tools, that are cross-platform including Android and iOS	CAB consensus
		Content formatted for readability irrespective of the quality of device used	CAB consensus
		Minimize use of formats (e.g., videos, complicated graphics) that have higher broadband needs	CAB consensus
		All material include content that addresses the needs of both: patients who are engaged in their care and also those not activated o engaged	CAB consensus
		Include questions to facilitate anonymous sharing of knowledge and personal stories and experience between the highly engaged and less engaged CHD patients	CAB consensus
		Build community that supports each other and future generations of patients	Community partners, CAB discussions guided by findings from semi-structured interviews

Theory-driven intervention components: Using the BCW framework, we mapped barriers to specialized care (identified through interviews and CAB discussions) to behavioral targets and intervention functions (**Figure 2**). This systematic approach enabled us to select six BCW functions (Education, Training, Environmental Restructuring, Modeling, Persuasion, and Enablement) and translate them into specific intervention components. For example, educational modules with analogies explaining CHD conditions address capability barriers (lack of knowledge), while peer narratives simultaneously address social opportunity barriers (modeling self-advocacy) and motivation barriers (building confidence and hope). We further mapped these intervention components to intervention objectives to develop a theoretical framework showing how intervention functions are hypothesized to impact outcomes (**Figure 3**).

Design of the digital tool:
*Digital Research Platform***:** The digital tool was designed and hosted on the Eureka Research Platform (University of California, San Francisco), a HIPAA-secure, NIH-supported infrastructure that integrates data collection and intervention delivery within a single platform [50]. Participants enroll remotely via electronic consent using QR codes or web links (UCSF IRB#22-36667).

Branding: The community partners discussed various options for name and logo of the digital tool and narrowed them down to four potential names: My Congenital Heart Care, Empower My Congenital Heart, My Congenital Heart Guide, Uplift My Congenital Heart. The CAB members suggested to include an arrow in the logo to reflect the primary goal of uplifting and empowering patients. Red, blue, and purple colors were chosen to reflect the diversity within CHD lesions and their uniqueness from other heart diseases. The design team developed four branding prototypes reflecting CAB priorities: upward arrows symbolizing empowerment and red-blue-purple color schemes representing CHD diversity (**eFigure 1**). Through CAB voting, 'Empower My Congenital Heart (EMCH)' with an integrated heart-and-arrow logo (option B-2) was selected.

Participant flow within EMCH: The intervention design enables recruitment through email, clinic flyers, social media, or community outreach using study-specific QR codes. After registration and electronic consent, participants engage via smartphone or web browser. Activities are delivered every 2 months, a schedule selected by the CAB to balance engagement and participant burden. Each activity cycle remains available for 2 months and includes surveys, educational modules, and optional linkages to wearables, smartphone data, and patient portals (**Figure 4**). Surveys gather self-reported data, feedback, and allow them to share stories or questions (**eTable 2**). Modules provide concise guidance from ACHD experts and patients to enhance confidence and knowledge in navigating CHD care (see below). Optional linkages enable participants to share their health data, supporting research and understanding of ACHD patient experiences and behaviors. For example, during the first 2-month cycle (enrollment to month 2), participants complete baseline demographic surveys, after which Module 1 (A Guide to Choosing Your Care Team) and optional linkages become accessible. During months 2-4, quality-of-life surveys become available, followed by Module 2 (Navigating Cardiologist Appointments) and optional linkages, if not already completed.

Core intervention components within EMCH (Figure 5). The following sections describe how each intervention component operationalizes the BCW intervention functions identified in **Figure 3**.
(1) Educational modules (addressing **capability** and **motivation** barriers)*:* Co-designed with the CAB, modules are developed around three core takeaways aligned with the COM-B framework: increasing knowledge about CHD and navigating health system (capability), enabling access to ACHD specialists (opportunity), and incorporating peer narratives to build motivation. Modules combine concise educational content with clinician-derived "Empowerment" messages and patient-derived "Peer Empowerment" stories to reinforce active self-management through confidence, social influence, and optimism, and may include brief interactive elements (e.g., trivia). Examples of "Empowerment" quote include "Often, over time you build strong relationships with the nurses, social workers, and care coordinators in the team who can help with insurance approvals, disability forms, etc." while that of Peer Empowerment include "When deciding whether to go to the emergency room, I call my cardiologist while on the way to discuss the situation. If my cardiologist says I don't need to go, I simply turn around. This way, I'm already en route if I do need to be seen." (Figure 5). Community partners identified seven priority themes to support health system navigation based on user needs that determined the content of the modules (**eTable 3**). The first seven modules (Year 1) cover core components related to CHD education and health-system navigation, mapped to BCW constructs. After completing the year 1 core modules, participants may continue to engage with additional modules (such as psychosocial concerns, work or travel considerations, diet, exercise, pregnancy/family planning, dental care, etc.); brief bimonthly "pokes" featuring peer stories, study updates, or CHD research opportunities; appointment nudges; or through surveys where they can share their stories. All materials are designed using a design guide (**eTable 4**) to ensure uniformity and consistency and enhance readability. Currently, all participants receive the same core educational modules in the same sequence. However, "Knowledge About My CHD Condition" module allows self-directed personalization where participants can select their specific CHD diagnosis (e.g., atrial septal defect, tetralogy of Fallot, single ventricle, etc.) and engage only with the content relevant to them.
(2) Appointment planning nudges (addressing **capability** barriers of forgetting routine visits): Embedded within the annual surveys, the gentle nudges prompt scheduling or completion of ACHD specialist visits.
(3) Personal digital medical passport (addressing **physical opportunity** barrier of centralized information)*:* The passport is automatically generated from baseline self-reported data about congenital heart diagnosis, pacemaker/defibrillator device type and manufacturer (if applicable), other medical comorbidity information, ACHD cardiologist name and clinic location, primary care physician name and location, and any additional relevant health details (e.g. oxygen saturation, allergies, etc.) (**Figure 6**). The passport serves as a centralized hub for all medical and provider information while also linking participants to curated community events, all EMCH resources (modules), the ACHD provider directory, and a secure feedback and contact form. The passport is always accessible via smartphone within the EMCH app and can be

shared with clinicians by displaying on-screen. As the passport data is self-reported and build from baseline surveys, users are encouraged to verify accuracy with their ACHD team while completing these surveys (functionality to update the passport information is under development).

(4) Peer connections and community support (addressing **social opportunity and motivation** barriers): Peer Empowerment quotes integrated throughout modules provide modeling for self-advocacy and build confidence. Community event listings connect participants to other ACHD patients by providing information about the local CHD walks, camps, support groups, and social media channels to reduce isolation. Before final inclusion, all peer-contributed content is thoroughly reviewed by the CAB members and the research team for authenticity, relevance, medical accuracy, tone, alignment with design objectives, privacy protection, and for removal of any distressing content. Currently, EMCH does not include open peer-to-peer messaging or unmoderated forums to ensure content quality and participant safety. All peer content is curated and vetted before being shared with the participants.

Iterative Refinements During Intervention Development: Throughout development, intervention features were refined based on pilot testing, CAB feedback, and adherence to digital health equity principles (**Table 5**). These refinements demonstrate the responsive, user-centered development process that shaped the final EMCH design.

Table 5: Iterative Refinements During Intervention Development			
Initial Design	**Refinement**	**Rationale**	**Data Source**
Monthly delivery of the module	Modules delivered every 2 months	Reduce participant burden while maintaining engagement	CAB feedback
Colorful icons/ imagery	Flat, minimalist icons	Enhance readability, reduce bandwidth needs, improve accessibility	Digital health equity principles + CAB feedback
Frequent reminders (9 total: 3 email, 3 push, 3 texts per module)	Reduced to 3 total reminders per module	Minimize intrusiveness, respect participant time	User testing + CAB feedback
Reminders sent until all activities completed (survey and modules)	Reminders sent only if module incomplete; most surveys are not re-prompted	Minimize intrusiveness for data collection while providing opportunities to engage with modules	CAB feedback
Digital passport surveys delivered at 3 months post enrollment	Digital passport surveys delivered at the time of enrollment	Maximize early engagement with digital passport from first access	User testing + CAB feedback
Clinician guidance and peer narratives labeled as "Tips"	Clinician narratives as "Empowerment" quotes; peer narratives as "Peer Empowerment" quotes	Emphasize empowerment and positivity as primary intervention goals	CAB feedback
Module content primarily informational	Added interactive elements (trivia questions, action items) within the modules	Enhance engagement and encourage clear, actionable takeaways	CAB feedback
Digital passport to include comprehensive data (CHD history, other medical history, all providers, medications, insurance)	Digital passport limited to pertinent medical and provider information	Simplify content to enhance usability and relevance; reduce data entry burden	Eureka platform team + CAB feedback

Engagement in EMCH: Engagement is supported through multi-modal communication (app notifications, email, SMS), with up to three reminders per activity cycle sent at varying times to accommodate different schedules and time zones. A unique feature is the bi-monthly 'Poke': a brief, variable-timing communication featuring peer stories, study updates, CHD research opportunities, or community-shared experiences. Content variability and unpredictable timing of the Pokes was a feature adapted from established Eureka workflow that enable intermittent reinforcement and maintain interest [50].

Data Security and Privacy: The Eureka Platform uses a 128-bit secure socket layer (SSL) protocol that protects all data transmission between the app and server users. Data is stored on HIPAA-compliant servers managed by UCSF with restricted access to essential research personnel, using multi-factor authentication with role-based permissions. Survey responses and engagement metrics are stored as separate csv files using a unique identifier but no personal identifiable information. Only authorized research team can link the de-identified data to individual participants. Participants can

withdraw from the study at any time through the app or by contacting the research team. Upon withdrawal, participants can request deletion of their data or allow de-identified data to remain for research purposes. Participants control whether their stories can be shared as Peer Empowerment content (explicit opt-in required). Wearable device data (FitBit) and patient portal connections require separate participant authorization and are governed by those platforms' privacy policies in addition to EMCH protections. Study data will be retained per UCSF IRB and NIH data sharing policies, after which it will be securely destroyed or permanently de-identified.

Discussion

Principal Results: We describe a theory-based, community co-designed approach to developing EMCH, a digital intervention promoting confidence and skills to enhance engagement in lifelong ACHD specialized care. To our knowledge, this is the first cross-platform (Android and iOS) digital tool specifically designed to address ACHD-specific barriers to lifelong specialized care. Our approach integrated evidence-based behavioral frameworks (COM-B/BCW) with extensive qualitative research (n=54) and community-based participatory design to map barriers to engagement and develop targeted intervention components. The CBPR approach ensured patient and clinician perspectives shaped all design decisions. EMCH enables convenient, passive content access using user-friendly design and behavioral economics (nudge) principles while fostering peer connections and community contribution.

Clinical Relevance and Expected Impact: Existing CHD digital interventions focus narrowly on symptom monitoring, exercise support, or transition readiness in young adults and lack theoretical grounding or rigorous evaluation [51,52]. EMCH addresses the full adult lifespan (18+ years) and targets the complete spectrum of barriers to ongoing specialist care, including those who never transitioned from pediatric care or were lost to follow-up. The intervention's systematic foundation in behavioral theory (COM-B/BCW) distinguishes it from information-only approaches by addressing psychological capability, social opportunity, and motivation simultaneously. If effective, EMCH could promote lifelong specialized care and reduce preventable ACHD complications, emergent hospitalizations, and mortality associated with care gaps.

Scalability and Sustainability: We aim to recruit and engage a representative ACHD population, particularly those with a high risk for gaps in care (young adults, men, rural residence, lower socioeconomic status, those living far away from CHD centers, etc.) and those not previously engaged in research. Mobile phones are nearly ubiquitous - 96% of Americans (and 94% of ACHD patients) in their twenties and thirties own a mobile phone, and reliance on them for online access is especially common among young adults, non-Whites, and lower-income Americans [22,53,54]. This provides us with a huge opportunity to enhance the reach and scalability of our digital health intervention to various subgroup of ACHD patients. With the use of digital health equity and diffusion of innovation frameworks and the versatility of options for our digital intervention (cross-platform low bandwidth content delivery with opportunities for translation, etc.), our intervention is likely to be relevant to the most representative population. Digital tools offer scalable solutions to supplement clinic-based care. EMCH was designed to augment, not replace, individualized patient-provider interactions by building engagement skills outside clinic visits. We selected the Eureka Digital Research Platform for its sustainability (NIH-supported, UCSF-owned), integration of recruitment through intervention delivery, and cost-efficiency supporting hundreds of concurrent studies. Unlike clinic-based navigator programs requiring ongoing personnel costs, EMCH's automated content delivery and peer-generated stories provide sustainable engagement with minimal marginal cost per additional user. This infrastructure enables cost-efficient delivery at scale while maintaining intervention fidelity.

How EMCH Differs from Existing Approaches: We selected BCW over alternative frameworks (e.g., Intervention mapping or the Consolidated Framework for Implementation Research) [55,56], because it provides flexible, evidence-based guidance for digital behavior change interventions without being overly prescriptive [57,58]. The BCW process enabled transparent documentation of our intervention's theory of action by systematically mapping behavioral barriers to specific intervention components using shared taxonomic language [30]. Integrating community-engaged approach with behavioral theory proved essential for moving beyond merely identifying known barriers [28]. Qualitative methods and community engagement revealed not just what barriers exist, but how to address them effectively. For example, while we knew many ACHD patients lack awareness of specialist care needs [5], interviews and CAB feedback showed that evidence-based information alone was insufficient. Participants needed peer stories and real-life scenarios to internalize the message's relevance. This insight led to "Empowerment" and "Peer Empowerment" quotes becoming core intervention components, using modeling to build confidence and demonstrate care's importance when patients feel well. The combined theory- and community-engaged approach can be resource-intensive but adaptable. Teams with limited resources can supplement qualitative work with rapid stakeholder consultation while maintaining the framework's core

strengths: preventing reinvention of existing content, simultaneously addressing engagement and implementation barriers, and ensuring intervention components meet users' actual needs.

Limitations: EMCH addresses patient-level barriers but cannot overcome system-level challenges such as ACHD specialist shortages, insurance coverage gaps, or geographic distance from specialized centers. The intervention is likely most appropriate for stable patients capable of self-management with remote guidance; patients with complex acute needs or severe cognitive impairment require in-person clinical support that digital tools cannot replace. The digital tool requires a smartphone or computer with internet access. While limited digital literacy is uncommon in the relatively young ACHD population (94% own smartphones) [22], and EMCH is available on web and native iOS/Android platforms with low-bandwidth design, the most vulnerable patients with care gaps may face barriers beyond digital intervention scope. However, by reducing routine educational burden for digitally engaged patients, EMCH may enable clinical teams to prioritize in-person resources for those with greater needs. The digital passport currently captures baseline data only and does not allow users to update information as their medical status changes, which may limit accuracy over time. We are developing update functionality for future versions and exploring integration with electronic health records to auto-populate verified clinical data. Although we incorporated diverse perspectives during development, we may not have captured all viewpoints from populations or organizations not initially included. The EMCH infrastructure supports continuous adaptation through participant feedback and research collaborations, enabling rapid implementation of new components (e.g., mental health modules, culturally adapted content). Currently, individuals with intellectual disabilities are excluded due to unique accommodation needs requiring caregiver-focused approaches.

Next Steps: EMCH launched in September 2024 and has enrolled 500+ participants. Ongoing process evaluation is assessing acceptability, usability, and preliminary engagement patterns across diverse ACHD populations. We are developing Spanish-language adaptation to reach the 15-20% of ACHD patients who are primarily Spanish-speaking. Following process evaluation, we will conduct a randomized controlled trial evaluating EMCH's effectiveness on completing ACHD specialist visits and improving knowledge, self-efficacy, and social connectedness. If proven effective, EMCH will be made available to ACHD patients nationally through partnerships with our community advocacy organizations and in diverse clinical settings.

Conclusions: The theory-based, community co-designed EMCH digital tool provides ACHD patients with evidence-based resources, peer support, and practical skills to become activated and engaged partners in their care. Ongoing process evaluation will identify the acceptability, feasibility, and satisfaction with the EMCH intervention components, enabling refinement and tailoring for future hybrid effectiveness trials. If proven effective, EMCH's approach can be adapted for other chronic conditions requiring lifelong specialized care, as the behavioral frameworks and intervention strategies address universal barriers to care engagement. The EMCH infrastructure also enables rapid recruitment of diverse ACHD populations for future research and health policy initiatives.

Acknowledgments

The authors would like to acknowledge the important contributions of the patients, families, health care professionals, and advocacy representatives who partnered as our community advisory board.

Disclosure of Delegation to Generative AI

The authors declare the use of generative AI in the research and writing process. According to the GAIDeT taxonomy (2025), the following tasks were delegated to GAI tools under full human supervision:
- Proofreading and editing
- Summarizing text
- Reformatting
The GAI tool used was: Claude Sonnet 4.5.
Responsibility for the final manuscript lies entirely with the authors.
GAI tools are not listed as authors and do not bear responsibility for the final outcomes.
Declaration submitted by: Anushree Agarwal

Author Contributions

A.A. and J.V. contributed to all aspects of the study design, and in preparing the initial drafts and revisions of the paper.
K.B contributed to the recruitment and retention of study participants, qualitative analysis, development of study activities, and study regulatory management.
K.M. contributed to the qualitative interview process, identification of necessary design objectives and intervention features for EMCH.
J.M, K.R., K.M., and P.A. contributed to qualitative analysis, conduct of the study and critical review of the manuscript.
P.K. contributed to the technical development and adaptation of EMCH study activities on the UCSF Eureka Research platform.
K.L., K.P., M.D.N, K.B.J., L.R., P.M., M.O, G.M.M, and M.G. contributed to the overall study design and critical review of the manuscript.

Supplementary Information is available for this paper.

Figure 1: Overview of the Digital Health Intervention Planning and Development Process
Behavioral frameworks (Behavior Change Wheel, Digital Health Equity, Diffusion of Innovation, and Behavioral Economics) were integrated with semi-structured interviews and an iterative design process with the community partners. This process optimized the development of a digital health intervention with key objectives to build patient activation and empowerment skills and promote lifelong adult congenital heart disease specialized (ACHD) care.

Figure 2: COM-B and BCW Framework for the Digital Intervention to Promote Specialized ACHD Care
Semi-structured interviews and community partners identified barriers to specialized ACHD care amenable to digital intervention and patient-centered goals. These were mapped to BCW to create a theory-driven approach for intervention development. This framework identified COM-B barriers to specialized care, behavioral targets to address those barriers, and intervention functions that informed the selection of specific intervention components within the digital tool.

Figure 2: COM-B And BCW Framework for the Digital Intervention to Promote Specialized ACHD Care				
COM-B Component	Identified Barriers (from interviews and CAB)	Behavioral Targets (What needs to change)?	BCW Intervention Functions*	Intervention Components within the Digital Tool
Capability — Psychological	Lack of knowledge about CHD; unable to find ACHD specialists; forget to schedule routine visits	Increase knowledge, help find ACHD specialists, reassurance	Education, Enablement, Persuasion	Educational modules; ACHD Clinic Directory link; ACHD appointment nudges
Opportunity — Physical	Difficulty keeping all medical history centralized and easily available	Provide secure, easily accessible location	Environmental restructuring, Enablement	Digital Medical passport with medical history and provider information
Opportunity — Social	Unable to advocate or connect with physicians; Feeling 'lonely' given CHD is rare	Prepared to advocate	Modeling Enablement	Peer narratives demonstrating self-advocacy; Peer connection opportunities through community event listings
Motivation — Reflective	Belief in unmet needs (e.g. family planning, travel, drugs, work/school, etc.); Social stigma and low confidence related to scars	Reassurance that needs can be addressed with ACHD team	Education Training/ Modeling	Educational content on life topics (pregnancy, career); peer success stories
Motivation — Automotive	Fear of being dismissed	Foster optimism and address readiness	Persuasion Modeling	Positive framing; peer narratives building confidence

*"Functions" in the COM-B model: Education, Persuasion (induce positive feelings or stimulate action), Training (impart skills), Environmental restructuring (change the physical or social context), Modeling (examples to aspire to or imitate), Enablement (reduce barriers).

Figure 3: Theoretical framework Hypothesizing the Impact of Digital Health Intervention Components on Outcomes

The intervention components (educational modules, digital medical passport, peer connections, and appointment nudges), delivered via web and mobile app, function as tools for education, training, enablement, persuasion, modeling, and environmental restructuring to enhance the Capability, Opportunity, and Motivation (COM-B) domains of adult congenital heart disease (ACHD) patients. We hypothesize that these components will support patient activation and engagement skills and lifelong specialized ACHD care, ultimately improving patient experience and health outcomes.

Figure 4: Participant Flow Through EMCH
EMCH is accessible via the UCSF Eureka Research mobile app or web platform. Participants first create a UCSF Eureka Research account (Step 1), then review and electronically sign the EMCH consent form (Step 2). Following consent, participants receive study activities every 2 months (Step 3), including surveys (participant data, feedback, and participant experiences), modules (clinician guidance and peer narratives, resources on topics related to CHD and health system navigation), and optional connections to wearables, smartphone data, and patient portals. Participants also receive a "Poke" notification roughly every 2 months to remind them of new activities (Step 4). Representative screenshots show the web-based landing page and mobile-app study information page.

Figure 5: Representative Core Intervention Components within EMCH
The screenshots show representative screens of the educational modules (with clinician guidance, "Empowerment", and patient-derived "Peer Empowerment" stories), appointment planning nudges (embedded within the surveys), and personal digital medical passport (a centralized hub for all medical and provider information while also linking participants to curated community events, all EMCH modules, the ACHD provider directory, and a secure feedback and contact form). Peer connections component of EMCH is integrated within the modules and community event listings.

Educational Modules: Clinician Guidance, 'Empowerment' and 'Peer Empowerments' **Appointment Nudge** **In-App Medical Passport**

Figure 6: Digital Medical Passport Built Using Self-Reported Data
This figure illustrates the type of health information easily accessible to participants at any time through the EMCH mobile app. By completing a series of surveys with self-reported data, participants build their own digital medical passport, a personalized hub for their vital health and provider information.

Self-Reported Information Within The Surveys
