Life Expectancy in the United States Returns to PrePandemic Levels

Harry Wetzler, MD, MSPH, Independent Analyst

Abstract

U.S. life expectancy at birth fell to its lowest point since 1996 during the pandemic. It rose in 2022 and 2023 but remained below the 2019 level. Abridged life tables were used to assess the results for 2024, based on CDC WONDER mortality data and Census Bureau population estimates. In 2024, life expectancy at birth increased to 79.13 years, and to 19.87 years at age 65. These gains have nearly reversed the declines seen during the COVID-19 pandemic.

Introduction

US life expectancies declined markedly between 2019 and 2021 to the lowest levels seen since 1996.[1,2] My results for 2023 and those from CDC/NCHS revealed that approximately 76% of the 2019-2021 declines were regained in 2022 and 2023.[3,4,5,6] The purpose of this study was to estimate US life expectancies for 2024.

Methods

Life expectancies for 2024 were calculated using the previously reported methods.[4] This update includes 2024 deaths reported through May 10, 2025.[7] Vintage 2024 population estimates were used.[8] Because data were anonymized and publicly available, approval by an institutional review board and informed consent were not required in accordance with 45 CFR §46. I followed the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) reporting guidelines.

Since the 2024 death data are incomplete, 5 weeks of data – April 12, 19, 26, and May 3, and 10, 2025, were modeled to project the number of deaths that actually occurred in 2024. This equation was fitted using SPSS[9]:

> ln(deaths) = constant + (coefficient/days)
> where days were numbered starting with 1 on April 12, 2025, and ending with 999,999 because the equation is asymptotic.

R squared values for all deaths and for females and males separately each exceeded 0.99. This model was selected due to its ability to capture transient spikes in weekly incremental death counts observed during the past two years. In 2024, there was a sharp increase of 58,518 deaths between the weeks ending March 30 and April 6, followed by smaller weekly increments of 148 and 303 deaths. Similarly, in 2025, a spike of 4,034 deaths occurred between April 12 and April 19, with subsequent weekly increases of 339, 204, and 115 deaths. The modeled total deaths were used to inflate the age-specific estimates.

On May 14, 2025, the CDC reported a 27% decrease in overdose deaths for 2024 compared to 2023.[10] The impact of this reduction on life expectancy in 2024 was estimated. Chiang's formula was used to calculate the standard error of life expectancy.[11]

Results

Through May 10, 2025, 3,071,731 deaths were reported in the US for 2024, a 0.6% decrease from 2023. A total of 3,071,784 deaths are projected to be reported for 2024, an increase of only 53 deaths.

Table 1 lists life expectancies at birth for the CDC/NCHS US life tables and those calculated in this and the two previous studies (the 2023 CDC/NCHS results are only reported in tenths of a year).

Table 1. US Life Expectancies at Birth

		Year					
		2019	2020	2021	2022	2023	2024
Total	CDC/NCHS	78.85	76.99	76.37	77.46	78.4	--
	This study	79.22	77.01	76.41	77.52	78.53	79.13
Female	CDC/NCHS	81.39	79.88	79.33	80.20	81.1	--
	This study	81.78	79.81	79.36	80.24	81.16	81.57
Male	CDC/NCHS	76.31	74.19	73.55	74.80	75.8	--
	This study	76.66	74.33	73.59	74.87	75.95	76.72

With one exception, the CDC/NCHS values are consistently lower. The largest discrepancies occurred in the year 2019 estimates. The median difference for years 2020-2023 was 0.05 years.

Table 2 lists life expectancies at age 65 for the published US life tables and those calculated in this and the previous studies.

Table 2. US Life Expectancies at Age 65

		Year					
		2019	2020	2021	2022	2023	2024
Total	CDC/NCHS	19.59	18.46	18.42	18.91	19.5	--
	This study	20.05	18.42	18.51	19.00	19.66	19.87
Female	CDC/NCHS	20.82	19.78	19.74	20.17	20.7	--
	This study	21.29	19.68	19.81	20.20	20.81	20.99
Male	CDC/NCHS	18.20	17.03	16.99	17.54	18.2	--
	This study	18.65	17.06	17.09	17.67	18.37	18.62

Again, the CDC/NCHS values are generally lower. The median difference for years 2020-2023 was 0.085 years.

The Chiang standard errors for the 2024 estimates for females are 0.011 years at birth and 0.008 years at age 65. For males the corresponding standard errors are 0.012 and 0.008.

If the 27% decrease in overdose deaths had not occurred, the life expectancies at birth would have been 0.25, 0.14, and 0.34 years less for everyone, females, and males respectively.

As seen in the figure, life expectancies at birth reached a plateau in 2014-2019 and the low points occurred in 2021. The subsequent increases replaced essentially all the declines. A similar pattern without the plateaus occurred in the life expectancies at age 65.

Discussion

US life expectancies in the US rose again in 2024 and almost all of the pandemic era declines have been erased. Yet it is noteworthy that an estimated 1,366,642 excess deaths occurred in the US between February 1, 2020, and December 31, 2022.[12]

Comparing the results of this study with CDC/NCHS data from 2019 to 2023 offers a useful benchmark for assessing the study's accuracy. For the years 2020 through 2023, the differences in life expectancy at birth were all within 0.15 years. The largest discrepancy in life expectancy at age 65 was 0.17 years. As noted in the Results section, this study's life expectancy values tend to slightly exceed the CDC/NCHS values.

Hanley raised the concern that reporting life expectancy to two decimal places implies nonexistent precision.[13] He proposed a simple formula for estimating the standard error of life expectancy at birth. When comparing margins of error computed using Chiang's method with those based on Hanley's approach, the differences never exceed 0.002 years. This close agreement suggests that observed increases in life expectancy between 2023 and 2024 reflect genuine gains. Moreover, even an extreme hypothetical—adding 10,000 additional deaths in the 0–1 age group—would reduce overall life expectancy at birth by only 0.22 years, further underscoring the robustness of these estimates.

The projected addition of 53 deaths has a negligible impact on the results as does the assumption that the age distribution of the additional deaths is the same as that in those already reported.

Conclusion

US life expectancies increased again in 2024, and pandemic declines have been largely erased. It is uncertain whether the 2014-2019 levels can be surpassed in the future.
