Correction of LMS Parameter Errors in Published Noonan Syndrome Growth Charts

Joseph H Chou MD PhD[*]

Mass General Brigham for Children, Newborn Medicine
Harvard Medical School, Boston MA

Growth reference curves were recently published by Cappa et al 2024 for children with Noonan Syndrome, including the LMS parameters which should allow calculation of expected values at any centile. However, closer inspection revealed significant problems with the LMS parameters, including calculated values that diverged to infinity or to imaginary numbers. In this brief report, I describe issues found, recalculate the LMS parameters based on the provided expected centile values, and quantify the improvement in performance and identify where the greatest discrepancies were found between the published and re-estimated LMS values. It is hoped that the Cappa et al will provide updated and corrected parameters to allow more confident use of this important clinical resource.

Keywords: Noonan syndrome, growth chart, LMS parameters

Introduction

Growth reference curves for Noonan Syndrome were recently developed from a 15-year single center study of 190 participants , including charts for four measures (height velocity, weight, height, and BMI) for males and females[1]. The supplementary materials included expected values at a number of centiles as well as LMS parameters to mathematically recreate the curves at arbitrary centiles[2].

During assessment of an electronic calculator created to facilitate use of these charts, some of the charts exhibited significant discrepancies between the expected values and values and those calculated from the LMS parameters.

This short technical brief describes the issues discovered and re-estimates LMS parameters from the reported centile data.

Methods

Source data was obtained from the Supplementary Tables S1a through S1h[1] and included for each measure, sex, and age the LMS parameters as well as expected measure values at the 3rd, 10th, 25th, 50th, 75th, 90th, and 97th centiles. The LMS method[2] allows calculation of measurement values X for any given L, M, S, and Z value. The parameters represent the Box-Cox power transformation for normalization of skew (L), the median value (M), and the coefficient of variation (S). Of note a Z score of 0 should represent the median (50th percentile), as can be seen from the equations (Figure 1).

$$X = M(1 + LSZ)^{1/L}, L \neq 0$$

or

$$X = Me^{SZ}, L = 0$$

Figure 1. Calculation of growth measurement X from parameters L, M, S, and Z

This study did not receive any funding. Competing interests: JHC is the developer of the PediTools website of growth calculators which generates revenue from Google Adsense; Google Adsense had no input on the content presented.

Those same equations can also be used to re-estimate the LMS parameters, given values of X and Z. To estimate the three LMS parameters, a minimum of three points would be required – seven X / Z pairs were available (from the seven expected centiles) for each LMS parameter. Regression estimation of the LMS parameters was performed using the `minpack.lm` R package for non-linear least squares regression[3]. Some convenience functions for LMS calculations were taken from the `peditools` R package[4].

Results

Discrepancies calculating values from LMS

The eight growth chart curves at the seven centile values were recreated by using the published LMS parameters (Figure 2 see also Supplementary Materials for larger versions of each panel). While most of the calculated values (red dots) were coincident with the expected centile values (black lines), there were discrepancies seen with the male BMI and weight curves, with the 97th percentile male BMI curve approaching infinite (and then imaginary) BMI after 17 years, indicating likely problems with the LMS parameters themselves. Less dramatic but clearly visible, the 90th percentile male BMI and higher percentile male weight curves all showed calculated values diverging away from the expected values.

By the definition of the LMS parameterization (Figure 1), a Z score of 0 should be identical to the M parameter. Plotting the difference between the M parameter and the reported 50th percentile for each chart and both genders at all ages revealed internal inconsistencies, most notable for the male BMI and weight curves at higher ages, but also with the female height velocity curve, also at higher ages (Figure 3).

Recalculation of LMS parameters based on reported centile values

Assuming that the reported centile values for all the curves were accurate (clearly, the male BMI curve approaching infinity was not accurate), the LMS parameters were re-estimated by least

Figure 2. Discrepancies between reported and calculated values. The reported values for the 3rd, 10th, 25th, 50th, 75th, 90th, and 97th percentile curves are in black; red dots are calculated from the published LMS values; blue dots are calculated from the re-estimated LMS values.

Figure 3. Difference between the reported 50th percentile value and the M parameter, which should be identical.

squares nonlinear regression from the seven available X / Z values from the centile curves, for all curves, ages, and sexes.

Recreated growth curves

The re-estimated LMS values were then used to recreate each of the percentile curves; the blue dots of the calculated values from the re-estimated LMS values now nearly precisely recreate the reported centile values (Figure 2).

Quantification of improved prediction

The mean absolute error (MAE) and maximum absolute error from the reported percentile values were also calculated for each of the calculated X values from both the originally published and the re-estimated LMS values (Table 1). For all charts, the re-estimated LMS parameters were non-inferior to the published LMS parameters at reproducing the expected values.

Comparison of published and re-estimated LMS parameters

The difference between the published LMS and the re-estimated LMS parameters was visualized (Figure 4). As expected, the greatest differences were seen in the plots with the greatest discrepancies seen in Figure 2 (red dots), but interestingly, the issues were not consistent for which LMS parameters were predominantly affected: the male BMI L, M, and S parameters; male weight L and M parameters; and female height velocity S parameters seemed to change most when re-estimated.

Discussion

The work of Cappa et al. addresses an important clinical need of evaluating expected growth outcomes in children with Noonan Syndrome, but there were significant inconsistencies between values calculated from the published LMS parameters and the expected percentile values, which compromise the clinical utility of these growth charts.

Most critically, the male BMI curve parameters produced mathematically impossible values (infinity and imaginary numbers) at higher ages and percentiles, with similar but less extreme

Table 1. Differences between reported values and values calculated from the published (`calc`) vs re-estimated (`est`) LMS values. The mean absolute value of the difference (MAE) and the maximum absolute of the differnece (MAX) are reported. The male BMI discrepancies from the published LMS values could not be calculated because of non-real number results.

measure	gender	calcMAE	estMAE	calcMAX	estMAX
bmi (kg/m2)	f	0.005	0.000	0.032	0.001
bmi (kg/m2)	m	NaN	0.013	NaN	0.132
height (cm)	f	0.034	0.000	0.137	0.001
height (cm)	m	0.032	0.000	0.213	0.001
height_velocity (cm/year)	f	0.008	0.002	0.080	0.010
height_velocity (cm/year)	m	0.002	0.000	0.013	0.001
weight (kg)	f	0.008	0.000	0.064	0.001
weight (kg)	m	0.177	0.012	12.574	0.215

divergence with the male weight curve. The M parameter diverged significantly from the 50th percentile values for male BMI and weight curves at higher ages, with milder divergence for the female height velocity curve.

To address these issues, nonlinear regression was used to independently estimate LMS parameters from the published expected percentile values in the supplementary materials. The re-estimated LMS parameters predicted the expected percentiles with substantially improved accuracy.

Given that growth charts are clinical tools that could directly impact patient care decisions, I believe it is important to bring these data inconsistencies to the attention of the medical commu-

Figure 4. Differences between published and estimated LMS parameters.

nity. Incorrect LMS parameters could lead to misinterpretation of growth patterns in children with Noonan syndrome. I attempted to contact the corresponding author via email in December 2024 and February 2025 to discuss these findings, but received no response. My hope is that the authors consider providing corrected supplementary materials to ensure the clinical utility and accuracy of this important resource.
