Running Head: Global prevalence of horizontal strabismus

Abstract

The prevalence of the two types of horizontal strabismus, esotropia and exotropia, varies considerably between studies. This variability has been attributed to factors such as geography/environment, research methodology, age of study subjects, and/or ethnicity. Comprehensive estimates of regional and global prevalences of esotropia and exotropia are lacking, making it difficult to recognize true patterns, trends, and etiologies. Our systematic review compiles prevalences and ratios of esotropia to exotropia from 315 population-based studies and 374 clinic-based studies. We analyze data to assess effects of ethnicity, geography, age, and we identify generational changes of horizontal strabismus. Major ethnicities differ in patterns and ratios of esotropia and exotropia prevalence, not only Caucasians and East Asians, but also Latinos/Hispanics, South Asians, Africans, and Native Americans. Compared to population-based studies, clinic-based studies underestimate exotropia frequency. By weighing prevalences according to the population size of ethnicities, we estimate the worldwide prevalence of horizontal strabismus in the current generation at 1.81% (138.5 million people), comprising 60.0 million people with esotropia (0.67%) and 87.5 million with exotropia (1.14%). In the previous generation, the worldwide prevalence of horizontal strabismus was 1.64% (86.5 million people), comprising 50.5 million with esotropia (0.96%) and 36.0 million with exotropia (0.68%). Esotropia and exotropia prevalences differ between generations within the same ethnicity, indicating that extrinsic factors can modify the underlying intrinsic (genetic) disposition.

1 Introduction

Strabismus is a relatively frequent ophthalmological condition that impacts visual function. Studies and review articles most often quote a prevalence of 2-4%.[32,75,79,113,142,150,179,196,210,251,255,261,268,271,290,293,318,373,399,485,448,455,501,545,569,577,596,614.645,665,685,753,776,777,807,815,817,845,868,A,B] However, population-based studies have reported the prevalence of strabismus within a surprisingly wide range, with extremes of 0.13% to 9.9% for normal populations (Fig. 1; Table 1). Previous attempts to estimate the global prevalence of strabismus[B,C,318] were based on a relatively small number of studies and resulted in estimates of 1.9% to 2.9%. Because of the large variability in primary sources, spanning two orders of magnitude, the true global prevalence of horizontal strabismus is unknown. Multiple reasons – not mutually exclusive – for the wide ranges have been considered. These include the methodology employed for examination, selection of non-representative cohorts, the classification of strabismus used, the age of subjects in the cohort, the geography, as well as the ethnicity of the cohorts examined. While older studies had suspected that geography was a factor, possibly due to differences in ambient light exposure with latitude,[100,109,344,372,436] some of the most recent and detailed reports concluded that methodological and/or age differences are mostly responsible for the wide variability between studies.[A-C,318,356] To obtain a more valid and global account of the prevalence of horizontal strabismus, we compiled and analyzed in this systematic review all reports that we could find, regardless of origin, language, and type of publication.

Strabismus is known to have a genetic component.[608] According to Hippocrates (ca. 460-375 BC), strabismus "runs in families."[339,810,815] The most frequent form of strabismus is horizontal strabismus, which consists of two types: esotropia (hereafter "ET," convergent deviation) and exotropia (hereafter "XT," divergent deviation). Consistent with the view of a

genetic component, the pioneering work of Ida Mann[482] concluded that the distribution of ET "strongly suggests a racial factor," and that "neither climate nor cultural practices … appear to influence it in any way." Other authors, however, proposed that horizontal strabismus may also have a considerable environmental component.[100,109,344,352,372,436,625,685,777,845] Since intensity and duration of sunlight affect eye growth and function,[254,481,497,499,512,566] differences in geography and climate are thought to be plausible factors that may contribute to the risk and the types of horizontal strabismus.[810]

Other factors that may explain differences in results between studies include the age of the study population, because strabismus prevalence is age-dependent,
[23,90,166,170,173,251,268,287,399,428,443,444,502,503,534,575,697,700,771,748,778,A,D] and studies vary in the age ranges of the cohorts examined. Additional factors that may be responsible for differences between studies are the definitions and methodologies used for examination,[61,287,293,697,A,B] and the epoch or decade of investigations because of generational changes.[62,448,498,857,A-C] Most of the older studies, and especially those that are widely cited, were conducted in countries with predominantly European (Caucasian) populations, and, more recently, with East Asian populations,[174,290,318,501,665,A] while other populations (Africans and South Asians) have received relatively little attention.[40,861] If ethnicity is a major determinant of ET and XT prevalence, then this must be considered to avoid Eurocentric bias when attempts are made to estimate the global prevalence of strabismus. Since certain forms of strabismus are associated with other diseases such as mental illness, schizophrenia in particular,[27,28,445,507,535,560,698,701,780] estimates of the total number of people with ET and XT, and past and current trends of prevalences are relevant for health policy beyond vision care.

Some investigators have compiled and compared the prevalence results and ET/XT ratios from previous reports; however, these studies considered only a small fraction (at most 15%) of the total number of studies on prevalence of ET and XT (Table 2), and rarely included reports written in languages other than English.[174,271,282,290,318,501,665,A,B] We reason that a systematic review and meta-analysis of all available data on the prevalence of horizontal

strabismus in a wide variety of populations and cohorts is more informative about the global prevalence and will help to rectify the relative neglect of ethnicities representing nearly half of the world's population. On the basis of this approach, we estimate the true prevalence of ET and XT in different countries and worldwide, and we determine patterns and prevalence changes over time that may help to identify risk factors and potential underlying causes for such trends and for the differences between populations.[381] To include a historical perspective, we review how knowledge about ethnic differences in horizontal strabismus evolved over the last century.

2 Methods

2.1 Methods of Literature Search/ PRISMA Guidelines

We followed the PRISMA guidelines for systematic searches and meta-analyses.[528] Our review protocol was registered in PROSPERO (CRD420251080354).[E] To identify relevant articles, we searched two databases, PubMed and Google Scholar. PubMed was queried with the keywords "strabismus" and "prevalence" which generated 2,653 records (July 1, 2025) and Google Scholar with the key words "strabismus", "prevalence", "esotropia", and "exotropia," which generated 7,880 records (July 1, 2025). We accepted all relevant reports that met the inclusion criteria (see below, 2.2), even when they were dissertations, conference proceedings, government reports, or were published in languages other than English (see flow-chart, Fig. 2). When not directly accessible or available through our institution's library, full-length texts were procured by interlibrary loan or by contacting the author directly. To find additional relevant texts that were missed by the PubMed and Google Scholar searches, we surveyed all references in each of the relevant reports for additional studies that matched our inclusion criteria. We used the link "similar articles" in PubMed to identify additional relevant sources and we examined each paper that cited a relevant report in the Web of Science Core Collection database ("Cited Reference Search")[F] for studies that had been missed. In total, 13,625 titles were screened. We ultimately found 689 reports that met the inclusion criteria. Original sources were read by multiple authors, leveraging the language skills among our team. There were no language restrictions as long as references or English titles or relevant key words appeared in searches; for example, we included 137 studies published in twenty different languages other than English: Chinese, Czech, Danish, Dutch, French, German, Greek, Indonesian, Italian, Japanese, Korean, Macedonian, Norwegian, Persian, Polish, Portuguese, Russian, Spanish, Swedish, and Thai, and we asked colleagues fluent in those languages to translate as needed.

2.2 Inclusion Criteria for Studies

We accepted all studies that report original and quantitative data on frequencies of esotropia (ET) and exotropia (XT) in human subjects, either obtained from population-based surveys, or from medical records in clinical settings. Reports had to be on humans; we did not consider prevalence studies on non-human primates,[411-412] and we did not include case reports. Studies were included only when they provided *quantitative* information about both ET and XT separately (not just combined ET and XT prevalence or prevalence of horizontal plus vertical strabismus). We did not include in our quantitative analysis studies that failed to provide exact information[439,508,674] or studies with only qualitative comments such as "most cases were esotropia", or "nearly all cases were exotropia."[244,626,647,683,814,865] We accepted both, population-based studies (screening of birth cohorts, schools or pre-schools, or military recruits, or inhabitants within a certain region such as an island, town or village), as well as clinic-based studies (surveys of medical records from patients seeking attention at a clinic). We kept these two types of studies separate, in two different tables and spreadsheets, and used them for separate analyses (see below, sections 3.2 and 3.8). In a few studies, the distinction between population- and clinic-based studies was questionable, due to a low response rate to home questionnaires or merely "inspection" by non-expert personnel prior to referral to an ophthalmologist, so that not the entire population was properly screened and would likely have given a significant underestimate of the true prevalence.[373,408,453,503] Accordingly, these four studies were listed as "clinic-based."

2.3 Data Curation

We compiled data in two main tables (Supplemental Tables S1 and S2): those from population-based studies (n=315) and those from clinic-based studies (n=374). Since many studies reported not only horizontal strabismus, but also the (relatively rare) occurrence of pure vertical strabismus (about 4-5% of all strabismus),[165,290] the data were verified to report prevalences exclusively for ET and for XT, but not pure vertical strabismus, and quantitative data on

prevalence were re-calculated and verified to provide prevalence values to a resolution of two places after the decimal point. We considered all relevant studies that met the inclusion criteria, but we omitted abstracts when a full-length publication of the same cohort had become available. We list all relevant studies by country and region, even when data from the same cohort was published more than once, but we used information from the same cohort only once in the data analyses. Duplicate publications of the same cohort are marked with italic font in Supplemental Tables S1 and S2.

Prevalence of a condition such as horizontal strabismus can refer to lifetime prevalence or to point prevalence.[755] Here, we report primarily on lifetime prevalence, but acknowledge that this is based at least in part on studies that report point prevalence. Reports of horizontal deviations in newborns are included in the Supplemental Tables S1 and S2 for completeness.[18,59,206,258,330,347,568,772] However, we did not include in our meta-analyses studies or cohorts that focused entirely on infants two years of age or less, for two reasons. First, it is controversial how many deviations in newborns are "genuine strabismus"[399] or may be an artifact – human judgement of newborn gaze may not be reliable and should take angle λ into account.[305,351,739,772,831] Many deviations are thought to be transient and typically resolve within a few days or weeks, although some of them are genuine cases of infantile/congenital esotropia.[59,251,258,347-350,399,568,741] Second, because only a fraction of horizontal strabismus is known to develop before the age of 2 years, [23,166,173,251,399,428,503,575,778,D] we excluded in our meta-analyses such studies (gray-shaded in our Supplemental Tables S1 and S2).[55,59,206,226,227,255,258,330,347,503,568,715,741,747,772] This does not mean that early types of horizontal strabismus such as the relatively rare infantile/congenital ET[290,810] were excluded, because they are represented in the many studies (n=56) with larger age ranges beginning at 0-2 years of age. For additional information, we included in our tables the location and number of subjects (cohort size), the age range, and the ethnicity (when such information was available). Data from clinic- (or primarily referral-) based studies are listed in a separate table (Supplemental Table S2), including the country and region/ethnicity, the relative contributions of ET and XT, and, if available, the number of subjects, and mean age or age range of subjects.

2.4 Data Analysis

    <u>1. Justification for Selection of Ethnicities.</u> We analyzed the main ethnic populations separately, extending the practice of previous studies and reviews.[113,147,149,170,197,255,290,361,380,436,510,545,665,773,793,859,A,D,G] Based on the compiled cases of ET and XT, we calculated the prevalence values for thirteen major ethnicities, obtained from 76 countries on six continents, according to the population-based studies. Some of these studies evaluated only one ethnicity, some evaluated multiple ethnicities, but did not report them separately, and a third group of studies evaluated multiple ethnicities, and reported them separately. Accordingly, we compiled most data by ethnicity, but in some cases had to present data in aggregate, for "multiple ethnicities," combined.

    In addition to the ethnicities of Caucasian, Native American, Inuit/Eskimo, Latino/Hispanic, African American, African, Middle Eastern, South Asian, East Asian, and Oceanian (Indigenous Australian and Melanesian), there were sufficiently large differences between African populations to warrant recognition of two types: the Niger-Congo-Bantu type in West Africa, and all other populations in Africa, consistent with the conclusions of anthropological, linguistic and genetic studies.[121,167,329,774] Likewise, there were significant differences between populations in the Northwest and Southeast of the Indian subcontinent that warranted a separation, again confirming genetic data,[91,383,402,475,655] and Persians have a different genetic history than other populations in the Middle East.[232] Therefore, a total of thirteen major ethnicities will be considered in this review, including two types in Africa, two types in the Middle East, and two types in South Asia.

    Caucasians in Europe, the Americas, South Africa, and Oceania were considered for the total Caucasian count; Europe includes Eastern Europe and Russia or the former Soviet Union. Israelis are listed among the Middle East category, because Jewish people are genetically closest to Middle Eastern populations.[595] We list Native Americans and Inuit/Eskimos separately, because these populations have distinct ancestries.[246,656,737] Although Nepal is geographically part of South Asia, we grouped Nepalis among the East Asian ethnicity, because

recent genetic evidence indicates that Himalayan valleys were largely populated from Tibet by East Asians, about 6,000 years ago.[374,820] For this review, we did not further divide the studies of indigenous people in Oceania, although recent work shows that the genetic make-up of the indigenous people in Australia and the Solomon Islands appears to differ from those in Papua-New Guinea, possibly due to divergence some 30,000 years ago.[398,477,738]

2. Meta-Analysis and Comparison of Prevalence between Ethnicities. Prevalence of ET and XT was compiled from population-based studies separately for each major ethnicity. We used R Studio, version 3.6.1, for statistical analyses (R Foundation for Statistical Computing, Vienna, Austria). To calculate estimates of pooled prevalence and 95% confidence intervals for both ET and XT we used the R-meta package, version 4.9-5, and the metaprop function.[87] The ET/XT ratios for small cohorts were adjusted to avoid having a "0" in the numerator or in the denominator (Supplemental Table S1).[758] We used random effects models with the inverse variance method for pooling and the logit transformation for proportions.[146,185] For ease of interpretation we back transformed and rescaled proportions to events per 100 observations. Analysis of the heterogeneity across studies was done using the Maximum-likelihood estimator, Higgin's I^2 and Cochran's Q method.[146,337] Publication bias was assessed by visual inspection of funnel plots.[209] In all cases, significance was defined at α = 0.05.

Subgroup analysis was conducted by ethnicity. Specifically, ethnicity was coded as a categorical variable with 13 levels: Caucasian, Native American, Inuit/Eskimo, Latino/Hispanic, African American, West Africans, all other Africans, Persians, all other Middle Easterners, South Asian (Northwest and Southeast separately), East Asian, and Indigenous Oceanian. To further quantify differences in ET and XT prevalence between the 13 ethnic groups, we followed up our meta-analysis with pairwise Pearson chi square tests for independence. To avoid a bias toward very large studies, we adjusted study size in the top 10% of studies to the 90th percentile prior to conducting our chi square tests. Because only two ethnicities, Caucasians and East Asians, have been examined and reported with sufficient numbers of studies over multiple generations in regard to ET and XT prevalence, we used separate chi square tests to evaluate prevalence differences between generations for these ethnic groups in a longitudinal analysis. We defined a

generation as 30 years based on the average number of years between the birth of a parent and their children.[782]

       3. Estimation of Global Prevalences and Preparation of a World Map. Prevalence of horizontal strabismus differs between ethnicities; ethnicity, therefore, must be taken into account when global prevalence is estimated. The data from Supplemental Table S1 was used to calculate the prevalence of ET and XT for each of the major ethnicities. Populations of the same ethnicity residing in different countries and continents were combined, and a pooled prevalence for each major ethnicity was calculated as explained above, with 95% confidence intervals, and plotted in a histogram, arranged by a decreasing ET/XT ratio. Our quantitative prevalence analysis considered 288 population-based studies from 76 countries around the world (after excluding 13 population-based studies on subjects two years of age or less and 14 additional studies reporting on duplicate cohorts). Based on the prevalences of each ethnicity, and the approximate total population size of ethnicities worldwide, we estimated the global prevalence for ET and for XT. We achieved this by extrapolation and weighing the population size of each of the major ethnicities (United Nations Report: List of countries by population).[H] Because of apparent generational (secular) changes in Caucasians and in East Asians, we separately estimated the prevalence of ET and XT in the *current* generation, based on studies published after 1995, and also in *previous generations*, based on studies published from 1846–1875, 1876–1905, 1906–1935, 1936–1965, 1966–1995, and 1996–2025, taking into account that some data from previous generations were reported with a long delay.[147,164,700,I]

       To generate a world map of ET and XT prevalence ratios, we considered those same prevalence data, but plotted them based on geography (country or region of residence). This map displays three "basic" types – prevalence of ET greatly exceeding XT (ET/XT ratio >1.5, blue), ET prevalence much lower than XT (<0.67, red), and ET having approximately the same prevalence as XT (ET/XT ratios of 0.67–1.5, yellow). Data from clinic-based studies were used to corroborate the patterns, using slightly lighter colors for countries where population-based studies are currently lacking, but clinic-based information was available.

4. Measurement of Equitability and Impact of Studies on Different Ethnicities. To assess whether different ethnicities are represented in an equitable fashion in studies of strabismus prevalence, and to quantify any existing imbalances, we calculated the number of studies per ethnicity and the percentage of the population that had been sampled, as a tool to assess whether ethnicities have been represented proportionally. We compiled the total number of subjects that had been screened, separately for each major ethnicity. We calculated the total number of subjects in population-based cohorts for each ethnicity and the number of subjects with medical records (clinic-based studies), again for each major ethnicity. We also calculated the number of cohorts per ethnicity, and those numbers relative to each major ethnicity's contribution to the world population.

To assess whether studies of different ethnicities have had commensurate impact, according to their contribution to the world population, and to assess whether certain ethnicities have been neglected, we measured the percentage of publications' citations as a fraction of the total citations. Citations were obtained on October 4-6, 2025 from the Web of Science Core Collection, Cited Reference Search,[F] as a measure of their impact.

5. Effect of Latitude. We used simple linear regressions to assess the effect of latitude/geography, by plotting the ET and XT prevalences (and the ET/XT ratio) against latitude. Four ethnic groups (Native Americans, East Asians, Caucasians in Europe, Caucasians in Australia) were eligible for this analysis, because these populations extend geographically over a significant north-south expansion, and there were sufficient data and numbers of studies available across latitudes. We performed our analysis separately for ET and XT, to determine which type of strabismus is mostly influenced, if at all, by latitude. We also investigated differences in prevalence between continents for Caucasians.

6. Effect of Age. We plotted the age ranges for cohorts to assess whether there were any apparent age differences between sampled ethnicities, and we calculated ethnic differences with and without studies that were on adults only. For all these analyses, we excluded the studies with exclusive focus on ages of 2 years or less, as explained in section 2.3. Prevalence

and frequency of ET vs XT was compared between studies that included children and those that focused entirely on adults or late teenage years. We also examined changes in ET or XT prevalence of ET/XT ratio changes in older adults, by reviewing studies that reported exclusively or specifically on subjects 55 years of age and older (n=5).[178,218,231,320,444]

7. Comparison of Data from Population-based and Clinic-based Studies. We compared the ratios of ET and XT prevalence from 288 population-based studies (which excluded 14 studies that reported on duplicate cohorts, and 13 studies that focused on ages ≤2 years) with the relative frequencies of ET and XT from 360 clinic-based studies (after excluding 12 reporting on duplicate cohorts and two studies reporting on ages 2 years and younger), weighted for cohort size as explained in section 2.4.3. This was done separately for nine major ethnicities: Caucasians, South Asians (Northwest), South Asians (Southeast), West Africans, all other Africans, Persians, all other Middle Easterners, Latinos/Hispanics, and East Asians. Because of small numbers of clinic-based studies (n≤1) and/or high heterogeneity, this comparison was not possible for African Americans, Native Americans, indigenous Oceanians, or Inuit/Eskimos. Nevertheless, this approach informs whether clinic-based ratios can be used as a proxy for population-based studies, a question that has been discussed for over 150 years.[149,173,174,179,390,753,773,811,841,857]

8. Changes in Prevalence between Generations: Comparison of 2–5 Generations. Several reviews comparing clinic-based percentages of ET and XT have reported changes (decreased numbers of strabismus surgeries) over recent decades.[62,102,126,149,150,158,161,195,236,332,366,376,433,448,458,464,498,663,719,720,824,857] To determine whether prevalences of ET and/or XT have changed over time, we compared prevalences in two major ethnicities that had sufficient numbers of population-based studies (data points) distributed over a longer time period (several decades), thus making them suitable for such a longitudinal analysis: Caucasians in Europe and North America, and East Asians.

2.5 Evaluation of Biases: Examiner Expertise, Study Design (Sampling), and Publication Bias

Bias can affect prevalence estimates at multiple levels and through diverse mechanisms.[182] To address potential biases in the estimation of ET and XT prevalence, we pursued the following approaches.

1. *Variability due to diverse Methodology/Classification*. Different studies apply different methodology and classifications, and the expertise of examiners can vary as well. For this reason, some investigators have proposed to consider only so-called "gold standard studies".[A,B] To determine whether such "gold standard studies" indeed yield results that differ significantly from those when all studies are considered, we compared them with studies examining cohorts of comparable age and ethnicity, and we used unpaired two sample t-tests to determine any statistically significant differences.

2. *Sampling Bias*. A potentially profound concern is that population-based studies are mostly school- or preschool-based, and such studies generally assume that all children have the same chance of being included in the sampled institutions. However, children with severe disabilities often do not attend normal schools and, therefore, may be missed.[110,113,122,255,287,333,369,575,582,808,A] Since infants and children with disabilities have an increased prevalence of horizontal strabismus (see section 3.11.ii), studies based on sampling of "regular" schools underestimate the true prevalence of strabismus. To estimate the effect size of this bias, we compared age- and ethnicity-matched studies with the rare studies that obtained data from birth cohorts (a more time-consuming strategy)[413] and therefore collect information from the entire (i.e., representative) population, not only of those children attending regular schools. There were thirteen such birth-cohort studies on Caucasians (on children older than 2 years),[65,147,287,394,420,428,491,575,624,649,732,748,833] three in the Middle East,[256,257,564] and one on African Americans.[147] Accordingly, this comparative analysis was possible only for Caucasians. We compared the means of ET and XT prevalence of the Caucasian birth-cohort studies with those from school-based studies with similar age ranges to determine the approximate effect size of any sampling bias.

3. Publication Bias and Meta-analysis Bias. Publication bias can be evaluated and recognized with funnel plots.[208,209,750,752] To evaluate publication bias and other meta-analysis biases, we compared prevalence numbers as a function of cohort size and prepared funnel plots in an ethnicity-specific design to detect and assess such biases.

3 Results

3.1 Literature Search Results

Our systematic search for relevant literature identified 689 eligible studies: 315 population-based studies from 76 countries (Supplemental Table S1; Fig. 2), and 374 clinic-based studies from 72 countries (Supplemental Table S2), most of them peer-reviewed journal publications or book chapters (n=645), but also government reports and other reports on websites, conference proceedings (n=10) and doctoral dissertations (n=27). We compiled many more studies than had previously been considered – including 137 studies published in languages other than English. We sorted the studies and entered data by continent, country, region or town, by ethnicity, and in chronological order within the following regions: Europe, North America, Latin America, Africa, Middle East, South Asia, East Asia, and Oceania. We provide in Table 3 the total number of subjects that were screened in the studies we compiled (Supplemental Table S1), and also the total number of patients whose medical records were analyzed (studies compiled in Supplemental Table S2). The percentage of the total population size for each ethnicity examined in population-based studies differed, and the mean cohort sizes also differed between ethnicities, ranging from 0.0012% (South Asians) to 1.24% (indigenous Australians), and mean cohort sizes ranged from 301 (Eskimo/Inuit) to 9,490 (Caucasians) (Table 3). Overall heterogeneity was high (I^2 = 96.7% for ET and 98.5% for XT, τ^2 = 0.9984 for ET, and 0.9867 for XT; for details, see Supplemental Table S3). Heterogeneity was reduced in most subgroups for specific ethnicities, indicating that ethnicity is a major contributor to heterogeneity. The only subgroups where heterogeneity was not reduced were Caucasians (ET) and East Asians (XT), likely due to generational changes described in section 3.12.ii.

3.2 Geographical and Ethnic Distribution of ET and XT Prevalence

1. Europe. The ET and XT prevalence was examined in 82 population-based studies (84 cohorts) from 24 European countries, published between 1867 and 2025, in Austria,[24,32,692] Belgium,[800] Bosnia,[627] Czechoslovakia,[515] Croatia,[394] Denmark,[250,251,356,684] Finland,[387,388,429,645,785] France,[731,743] Germany,[163,164,179,240,241,258,303,395,678,693,695,702,744,775] Greenland,[201,J] Hungary,[809] Ireland,[196] Moldova,[599] Netherlands,[K] Lithuania,[539] Norway,[65,343,L] Poland,[M] Portugal,[435,N] Romania,[331] Russia,[474,506] Spain,[181,491] Sweden,[10,61,226,227,266,293,342,416,428,439,446,573,575,582,649] Switzerland,[249,268,806] and the UK.[55,112,113,287,347,354,565,581,624,742,748,779,787,833,839] The cohort-weighted ET prevalence for Caucasians (over 2 years of age) in Europe was 2.065% (1.7917– 2.3771%, 95% CI), the XT prevalence was 0.6247% (0.5045–0.7733, 95% CI), resulting in an ET/XT ratio of 3.31. The prevalence of ET in Caucasians residing in Europe (2.065%) was significantly higher than in Caucasians who reside in continents other than Europe (Random effects model, p=0.0001), with ET prevalences of 1.553% in North America, 0.725% in Latin America, and 1.676% in Oceania (see below).

2. North America and Caribbean. We found 35 population-based studies, reporting on 45 cohorts in Canada, the USA and Caribbean, published between 1925 and 2013, with 22 studies on Caucasians: five in Canada,[380,420,421,667,837] and 17 studies in the USA.[59,105,147,166,170,200,255,330,414,510,536,568,741,772,D,O,P] Five studies were on Native Americans,[152,271,437,489,830] and two studies on Inuit/Eskimos.[380,835] There were nine studies on African Americans,[147,170,187,255,259,545,631,632,D] three studies on Latinos/Hispanics,[155,170,545] one on Asians,[507] and two on multiple ethnicities.[657,I] Some of these studies examined different ethnicities separately (Caucasian, Native American, Inuit/Eskimo, African American, Latino/Hispanic, and Asian). Caucasians and Inuit/Eskimos had the highest prevalences of ET (1.553%, 0.9381–2.1063% CI, and 1.997%, 1.7741–5.0557% CI, respectively), while African Americans had a lower ET prevalence (1.348%, 0.9933–1.8257% CI), and Native Americans (in all the Americas) had a very low ET prevalence (0.357%, 0.2018–0.6302% CI), and a very high XT prevalence (1.32015, 0.6793–2.5499%). African Americans had a higher XT prevalence than Caucasians in North America (1.2658%, 0.9527–1.6800% CI vs. 0.9381%, 0.6339–

1.3862% CI). African Americans had a much larger overall prevalence of horizontal strabismus (3.006%) than Africans in West Africa (0.9004%) or in other parts of Africa (0.902%, see below).

3. Latin America. We found 20 population-based studies that reported on 23 cohorts in Latin America, published between 1961 and 2024. Six studies reported on mostly Caucasians.[95,168,186,690,694,726] Ten studies reported on cohorts of multiple ethnicities, mostly Latinos/Hispanics,[171,172,238,270,384,490,505,537,583,Q] three reported exclusively on Native Americans,[99,272,790] and one reported on East Asians.[97] Latinos/Hispanics (in North and South America combined) had a prevalence of 1.7479% for ET (0.809%, 0.5826–1.122% CI), and 0.9389% for XT (0.5554–1.583% CI). Caucasians in Latin America had an ET prevalence of 0.725% (0.5681–0.9258% CI) and an XT prevalence of 0.5577% (0.3206–0.9684 CI). Native Americans in Latin America had a low ET/XT ratio – XT considerably exceeding ET – similar to Native Americans in North America (described above), and therefore these studies were combined because of the relatively small number of studies.

4. Africa. We found 37 studies reporting on 35 cohorts in 16 African countries, published between 1898 and 2024. The studies in northeast, central and south Africa are from Egypt,[9,214] Ethiopia,[242,275,768] Kenya,[R,S] Lesotho,[280] Madagascar,[71] Namibia,[252] Rwanda,[843] Somalia,[11] South Africa,[551] Sudan,[49,760,863] and Tanzania.[410] The studies in West Africa are from Congo,[663] Gabon,[341] Ghana,[13,423,557] Liberia,[335] and Nigeria.[2,15,22,33,34,41,70,76,79,80,86,153,225,T] The prevalence of horizontal strabismus in most populations in Africa is low, much lower than in major populations in Europe or in North America – the prevalence is 0.9004% in West Africa and 0.902% in other parts of Africa. While West Africans have a lower ET prevalence with 0.366% (0.238–0.5609% CI), and a somewhat higher prevalence of XT with 0.5344% (0.3295–0.8654% CI), this is opposite for people in the other parts of Africa where XT prevalence is significantly lower than ET prevalence: XT prevalence is 0.3692% (0.2232–0.61% CI), while ET prevalence is 0.541% (0.3182–0.9184 CI). The ET/XT ratio in West Africa (Niger-Congo-Bantu populations) is 0.68, while it is more than twice, 1.47, in the North, East and South of Africa, a significant difference (p=0.018, t-test). The reduced ET prevalence largely correlates with the genetically distinct Niger/Congo/Bantu-speaking populations in the western and central regions of Africa.[121,329,610,774]

5. Middle East. We found 36 population-based studies (reporting on 36 cohorts) from ten countries in the Middle East that were published between 1971 and 2024. One study was from Azerbaijan,[12] 17 from Iran[184,228,229,248,308,316,317,319,320,369,594,643,846-849,U] – some of these were recently reviewed,[403,679] three each were from Iraq,[8,307,544] and Israel,[256,257,564] one each from Jordan,[463] Oman,[457] and Palestine,[430] three from Saudi Arabia,[16,81,89] one from Syria,[281] and five from Turkey.[66,122,132,301,784] As is apparent in Supplemental Table 1, most Middle Eastern populations (Arabs, Turks, Jews, Kurds) have a higher ET prevalence (1.038%, 0.7086–1.5167% CI) than XT prevalence (0.6634%, 0.4156–1.0573% CI), while this is reversed in Azerbaijanis and Persians, who have a much higher XT prevalence (1.488%, 0.9236–2.3889% CI) than ET prevalence (0.577%, 0.477–0.69695 CI). The ET/XT ratio in Persians and Azerbaijanis is 0.39, while it is 1.56 in all other populations of the Middle East – a highly significant difference (p=0.000026, t-test).

6. South Asia. We found 25 population-based studies (reporting on 25 cohorts) from South Asia, published between 1961 and 2025, from three countries: Bangladesh,[63] India,[26,29,35,68,94,176,177,296,300,328,393,400,427,509,530,546,552,652,688,733,796] and Pakistan, including Afghan refugees in Pakistan.[72,73,716] Thus, the information on the South Asian ethnicity is relatively sparse.[861] In South Asians, horizontal strabismus has a remarkably low prevalence of 1.0358% in the Northwest of the Indian subcontinent and 0.9028% in the Southeast. However, similar to the horizontal strabismus in Africa and the Middle East, two distinct patterns are present in South Asia, with the Northwest having more ET than XT, while the Southeast has more XT than ET. In the Northwest of the Indian subcontinent, the prevalence of ET was 0.578% (0.3812–0.8761% CI), and the prevalence of XT was 0.4578% (0.2361–0.8859% CI), with an ET/XT ratio of 1.26, while in the Southeast, the prevalence of ET was 0.267% (0.1596-0.4464% CI), and the prevalence of XT was 0.6358% (0.3328–1.2112% CI), with an ET/XT ratio of 0.42 – less than one third of the ET/XT ratio in the Northwest (a borderline significant difference (p=0.0597, t-test), likely due to the small number of studies in the Northwest (n=6). Figure 4 shows how the distribution of ET and XT prevalence on the Indian subcontinent differs between the Northwest and the Southeast.

7. *East Asia*. We found 61 studies that reported on East Asians (63 cohorts), published between 1954 and 2021. We included the Nepalis among the East Asian category, because gene flow into Nepal occurred primarily via Tibet rather than via northeast India.[374,820] Most studies (n=24) in East Asia were from China,[142,144,206,230,261,323-325,375,378,432,449,454-456,459,604,620,705,821,822,864,866,867] followed by twelve studies from Japan,[282,314,360,473,493,501-503,554,555,687,844] six from Nepal,[563,607,724,725,727,728] six from South Korea,[311,443,444,639,855,856] four from Malaysia,[148,278,630,769] four from Thailand,[371,419,470,763] two from Singapore,[150,151] one from from Laos,[130] and one from Vietnam.[611] East Asians have an ET prevalence of 0.309% (0.2595–0.3674% CI), and an XT prevalence of 1.1395% (0.8976–1.4456% CI). East Asians have an ET/XT ratio (0.27) that is ten times smaller than that in Caucasians (2.83). East Asians thus have one of the highest XT prevalences and lowest ET prevalences when compared with other ethnicities. Recent upward trends of XT prevalence in China and Nepal will be discussed in Section 3.12.ii.

8. *Oceania.* We found 19 population-based studies (reporting on 30 cohorts) from Australasia and Melanesia, published between 1955 and 2016 in five countries: Australia,[110,345,447,465,481,484,665,666,677,A,V,W] Fiji,[G] New Zealand,[56,485,732] Papua-New Guinea,[X] Tokelau Islands,[216] and Solomon Islands.[802] Because of the multiple ethnicities involved (and the differences between these ethnicities), the prevalences are compiled separately by ethnicity in Supplemental Table S1. The prevalence of horizontal strabismus is very low in indigenous populations in Australia and South-East Asia (Philippines, Malaysia). The prevalence of XT (0.222%, 0.0944–0.5214% CI) is larger than that of ET (0.134%, 0.0585–0.3065% CI). A single study of indigenous people in Papua-New Guinea revealed a larger ET prevalence (0.1%) than XT prevalence (0.04%). Caucasians in Oceania (n=7 studies) have an ET prevalence that is lower (1.676%) than in Europe (2.064%), but similar to that of Caucasians in North America (1.553%). East Asians in Oceania have prevalences very similar to those of East Asians residing in East Asian countries.

3.3 *Comparison of Ethnic Differences in ET and XT Prevalences*

The results of the ET and XT prevalences for the different ethnicities from Supplemental Table S1 are summarized in Figure 3. We compare the cohort-size weighted ET and XT prevalences for the 13 main ethnicities in a bar graph, arranged by decreasing ET/XT ratio. Some ethnicities have much more ET than XT, some populations have a similar ratio, and some ethnicities have much more XT than ET (Fig. 3).

Note that ethnicities do not only differ in the relative differences in ET and XT prevalence and ratios, but also in the absolute percentages of horizontal strabismus. Africans, South Asians, and most indigenous people of Oceania have much lower horizontal strabismus prevalences, especially of ET, than the other ethnicities. A low horizontal strabismus prevalence is further supported by studies that did not distinguish ET and XT prevalences, such as for Africans in Tanzania,[825] Egypt,[214] Ethiopia,[252,516,712] Ghana,[576] Nigeria,[42,759] Rwanda,[706] African Americans in North America,[781] and also for South Asians.[74,140,188,297-299,405,424,425,467,556,567,598,629,721,722,729,734,788,789,791] Latinos/Hispanics and Middle Eastern populations have an intermediate prevalence of horizontal strabismus, higher than the above-mentioned populations, but lower than in Caucasians and East Asians. This conclusion is further supported by studies that, due to a lack of distinction between ET and XT prevalences, did not qualify for inclusion in the meta-analysis.[180,181,670,812,829,853]

3.4 World Map of the Horizontal Strabismus Prevalence (ET/XT Ratio)

As mentioned above, the studies on ET and XT prevalence can be sorted into three types based on the ET/XT ratio: Those with a much larger ET than XT prevalence (type 1 – blue: >1.5 ET/XT ratio), those with a much larger XT than ET prevalence (type 2 – red: <0.67 ratio), and an intermediate type where XT and ET are approximately equal (type 3 – yellow: ratio of 0.67–1.5). Using the geographic data compiled in Supplemental Tables S1 and S2, we generated a world map of horizontal strabismus prevalence. The highest ET/XT ratio is in countries with mostly Caucasians, but also in parts of Africa, the Middle East, Pakistan, and Northwest India, while the lowest ET/XT ratio is among East Asians, Native Americans, Persians, South Asians in the Southeast of India, and populations in West Africa (Fig. 4).

3.5 Geographic Distribution of ET and XT Prevalence – Is there an Effect of Latitude?

Previous work suggested that geography/latitude may be responsible for, or contribute to, the differences in prevalence between studies, presumably because the amount and pattern of sunlight can affect various ocular parameters.[69,75,100,109,254,344,372,436,461,481,497,499,512,566,673,810] Therefore, we examined whether latitude is associated with the ET/XT ratio. To minimize the confounding variable of ethnicity, we compared latitude within those ethnicities that distribute over a major north-south expansion. Latitudinal ranges of the ethnicities we were able to assess were from 60.2° N to 38.7° N (Europeans), 37.7° N to 3.1° N (East Asians), and 64.3° N to 12.7° S (Native Americans). We did not find any significant trends or correlations: R^2 values of 0.0003 and 0.0004 for Europeans and East Asians, respectively, (Fig. 5A-B) and an R^2 value of 0.0596 for Native Americans (but this reduced to 0.0004 when one outlier study was removed from the regression analysis, data not shown). We also confirmed the latitude data (from 27° S to 46° S) collected by Lance and Mitchell[436] for Australians – nearly all of them Caucasians. We conclude that latitude has no effect on the ET/XT ratio. For a plausible alternative explanation for increased XT in Caucasians living outside of Europe, see section 4.2.

3.6 Changes in ET and XT Prevalence and Frequency with Age

Previous investigators suggested that differences in the ages of cohorts may explain, to some extent, the variations in results between studies and populations.[251,287,318,575,A] To determine the extent to which age may be responsible for the prevalence differences between studies on different ethnicities, we compiled the age ranges for study cohorts and plotted them for several of the major ethnicities (Fig. 6A-F). The large majority of studies we reviewed concentrated on the age range of 3-12 years (n=273/288, 94.8%), which includes the age when the peak of prevalences has been reached, and it is prior to the drop-off of ET prevalence around puberty/adolescence.[90,166,251,268,429,444,826] When the studies that focused only on adults, from various ethnicities, were removed from the ethnicity analysis (n=13/288), our results did not

change, indicating that the (relatively few) studies reporting on adults-only are not responsible for the differences between ethnicities.

Our review of studies that compared multiple age groups showed that the prevalence of horizontal strabismus differs with age in distinct patterns.[90,142,166,170,250,251,268,286,287,318,429,443,444,502,503,510,574,575,771,857,D,I] Prevalence of both ET and XT is lower in the first three years of life, increases subsequently, and most studies report that ET prevalence decreases during or after puberty.[907,166,251,268,429,444,826] In Caucasians in Europe and North America, ET prevalence was 1.32% in ages 0.5 to 3 years (n=8 studies), which is about half of the ET prevalence of 2.26% at 4 years and older (n=89, p=0.014, unpaired t-test). Likewise, XT prevalence was 0.47% in the younger age group (n=8), compared to 0.95% in the older age group (n=88, p=0.012). The likely reasons for some of these changes with age are discussed in section 4.2.

Most studies report that XT prevalence increases in the elderly,[178,218,231,251,282,356,469,658,671,D] but there is some discrepancy between studies whether the prevalence of ET or XT changes already in middle-aged adults, or whether XT is more frequent (and ET less frequent) only in older adults. In East Asians, there is only a small further increase of XT in older age.[444] In our review, we found a total of 15 studies that reported ET and XT prevalences specifically in adults or in adults and adolescents, in several ethnicities: Caucasians, African Americans, West Africans, East Asians, South Asians, and Persians.[12,68,97,200,216,241,282,319,320,331,341,356,742,744,D] In 11 of the 15 adult cohorts, ET prevalence was lower, while it was higher in three studies, and there was no difference in one. In eight cohorts, XT prevalence was lower in adults, while in six other cohorts, it was higher, and in one there was no difference when compared with the prevalence in children of the same ethnicity.

In the population-based studies that specifically examined adults 55-60 years of age or older, for Caucasians[356,D] and African Americans,[D] and for Persians,[317,320] the XT prevalence was 2-3fold higher than in cohorts of younger-age adults (p=0.0146, paired t test). Furthermore, when we examined the ratio of ET/XT in adults 60 years or older from five relevant clinic-based studies on Caucasians,[178,218,231,469,658] we found that in those five studies, the proportion of

XT was much higher (49.3%) than would have been expected based on the XT proportion at younger ages in the same ethnicity (26.8%, n=103), and this difference of the proportion of XT was highly significant (p=0.00040, unpaired t-test).

3.7 Gender Differences in Horizontal Strabismus

Can gender differences in the prevalence of strabismus explain differences between reports? While there are some reports of a gender difference in horizontal strabismus, mostly of a female bias towards XT,[128,157,170,173,286,291,340,382,404,422,578,579,815] nearly all of these studies were clinic-based and had relatively small cohorts. Our recent systematic review and meta-analysis of gender in horizontal strabismus (based on 73 population-based studies)[441] found no difference in the prevalence (2.56% for males, 2.58% for females) – confirming the conclusions from large-cohort population-based studies[147,343,443] that there is no gender difference in prevalence of strabismus, although there is a significant female bias in the clinic.[441]

3.8 The ET/XT Ratio according to Clinic-based Studies: Comparison with Population-based Studies

While clinic-based studies do not inform about the prevalence,[390] they allow investigators to obtain information about the numbers of patients that seek and receive medical attention at a clinical facility – thus providing information about the relative frequency of ET and XT seen in the clinic. We compiled such information from 360 studies conducted in 72 countries (after excluding 12 studies that reported on the same cohort and two studies that reported exclusively on subjects two years of age or younger, Supplemental Table S2). In Europe, we found 72 clinic-based studies; from Austria,[699] Bosnia,[415,654] Denmark,[251,292,648,778] Finland,[494,646] France,[165,355,622,634,638,640] Germany,[193,340,391,703] Greece,[154,805,868] Hungary,[746] Ireland,[359,628,Y] Italy,[127,265,754] Netherlands,[173,382,399,792,Z] North Macedonia,[AA] Poland,[47,422] Portugal,[253,284,538] Romania,[527,BB] Russia,[794] Spain,[519,520,CC] Sweden,[18,315,417,618] and the UK.[23,112,128,131,178,224,273,344,363,401,464,513,542,559,621,747,753,771,828,840] There were 59 studies from North America, with 39 studies on

Caucasians,[17,28,85,93,108,119,169,218,221,231,239,247,286,289,321,361,362,451,469,492,532-534,619,623,644,658,660,676,696,697,704,772,824,832,859,DD] one study on Native Americans,[25] six on African Americans,[279,451,623,644,691,859] four on Asians,[361,362,623,644] six on mixed or multiple ethnicities,[100,260,361,362,540,707] and four on Latinos/Hispanics.[346,623,644,EE] We found 27 studies in Latin America, on Native Americans,[574,FF] Caucasians,[517,543,FF] Latino/Hispanic or mixed race,[21,191,198,294,389,431,468,521,528,529,587,597,600,617,668,669,671,799,869,GG,HH,II] and populations of African descent.[460]

There were 24 studies from North/East/South Africa on Africans/Arabs,[3,50,98,212,213,215,264,304,488,517,541,569,577,681,723,773,860,FF,JJ,KK,LL,MM] on Caucasians,[109] and mixed ethnicities,[773] and 28 studies from West Africa.[20,75,86,103,106,160,194,199,203-205,406,547-550,570,579,580,585,589,591,613,NN,OO,PP,QQ,RR] We found 45 studies from the Middle East.[1,3,4,30,36,37,43-45,46,48,51-53,57,83,88,123,124,136,174,175,184,222,234,281,302,352,358,366,397,404,514,553,571,588,637,643,651,661,682,850,851,SS,TT]

There were 41 studies from the Northwest of South Asia, with one study from Afghanistan,[54] twelve studies from Northwest India,[38,277,471,495,518,525,680,686,689,711,735,797] and 28 studies from Pakistan.[4,5,58,64,77-78,107,139,141,338,364-365,385-386,472,478-480,664,708-710,713-715,717-718,730] We found 19 studies on South Asians in Southeast India.[60,69,96,133,149,157,189,192,267,283,300,328,558,561,641,784,795,804,823]

In East Asia, we found 17 studies from China,[102,135,143,145,190,207,262,322,376,377,438,448,783,819,852,857,858] two studies from Indonesia,[233,636] twelve from Japan,[263,426,476,498,500,503-504,517,526,584,761,FF] seven from South Korea,[137,156,310,373,408-409,453] and eleven studies from Malaysia, Phillipines, Singapore, Thailand or Vietnam.[118,138,148,149,367,392,452,606,653,770,816] In Oceania, we found an additional nine studies.[56,202,274,344,436,482,601-602,W]

Our analysis shows that the estimated population-based ET frequency was lower (overall by 13.8%) than the frequency obtained from the clinic-based studies (Fig. 7). Conversely, the population-based XT prevalence was higher than the clinic-based estimate (by 13.8%). In other words, clinic-based studies underestimate XT frequency, compared with population-based studies (Fig. 7A). This pattern was consistent throughout all ethnicities, although the margins varied: The ET frequency in clinics was only slightly higher than in

population-based studies when the population had a large ET/XT ratio, while the deficit for XT in the clinic was substantial in ethnicities with large fractions of XT (23.3% difference in Persians, 17.0% in Latinos/Hispanics, and 15.2% difference in West Africans, Fig. 7B). This suggests that people with XT present less in clinics than people with ET; patients with XT (or their parents) may feel less of an urgency to visit clinics than patients with ET.

3.9 Impact of Studies reporting Prevalence in Different Ethnicities

We found many more population-based studies on Caucasians (n=115), most of them in Europe, than on any of the other major ethnicities (for which n ranged from 2-61 studies, Fig. 8A). Only Caucasians have been consistently examined over several (five) generations, and East Asians for the last two generations (Supplemental Table S1, Fig. 8A). We also found that the population-based studies on Caucasians (especially in Europe and North America) have had significantly more impact – being cited disproportionally, approximately 3-fold more ~ 40% of all citations) than their equitable share of the world population (which is ~15% for Caucasians, United Nations).[H] Nearly all other ethnicities were underrepresented in the number of studies and their impact, especially populations in Africa and in South Asia (Fig. 8). Specifically, Caucasian's impact is at 313.0% of equitable impact, Hispanics/Latinos are at 117.9%, East Asians at 73.3% of equitable impact, South Asians at 52.9%, Middle Easterns at 51.3%, and Africans trail at 34.5% (Fig. 8B), when citations are measured as a proxy for the relative impact (equitable impact = 100% of the contribution of that ethnicity to the world population). As can be seen in Figure 8A, the number of studies for neglected ethnicities (non-Caucasians) has been increasing in the last 1-2 decades, so the current imbalance is likely to improve in the future.

3.10 Role of Socioeconomic Status (SES).

We found several studies that attempted to explore whether SES is associated with horizontal strabismus, but results were inconsistent: some investigators reported a higher strabismus prevalence or frequency of diagnosis/treatment with lower SES,[210,317,443,462,466,522,609,771,A,UU] while

others found no association between SES and horizontal strabismus prevalence or frequency,[163,287,311,443,665,700,805] and one study reported very low strabismus prevalence with low SES.[177] When ET and XT were assessed separately, results also varied: one study reported a *higher* ET prevalence with lower SES,[771] while another one found a *lower* ET prevalence with lower SES,[833] and several studies reported a higher XT prevalence with lower SES.[147,318,A,B] The potential confounding of SES and ethnicity in the context of ET and XT prevalence will be discussed in Section 4.4.

3.11 Estimation of the Effect Size of Biases

To assess potential biases in the prevalence analyses, we followed three strategies, including a comparison with so-called "gold standard" (expert) studies, a comparison with birth-cohort studies, and an analysis of funnel plots for publication bias and meta-analysis bias.

i. Comparison with "Gold Standard" Studies according to Sharbini (2015).[A] Some investigators have argued that population-based studies in which a highly qualified examiner administers the tests for strabismus would be more accurate or valid, and they recommend considering only those studies with such a "gold standard" status.[A,B] When we compared the results of "gold standard" studies with the overall results of ethnicity-matched studies, we did not find any statistically significant differences between the two groups using unpaired Student's t-tests.

For Caucasians in Europe, ten "gold standard" studies were identified by Sharbini (2015)[A: 10,61,287,394,416-417,428,429,787] These gold standard studies had an ET prevalence of 2.26 ± 0.26% (SEM) and an XT prevalence of 0.76 ± 0.19%. The non-gold standard studies for Caucasians (n=51) had an ET prevalence of 2.64 ± 0.22%, and an XT prevalence of 0.67 ± 0.08%. We found no statistically significant difference between the two types of studies (Student's t-test, in both cases p > 0.10).

For East Asians, there are eight "gold standard" studies according to Sharbini (2015)[A:150,323-324,432,459,501,563,705] They have an ET prevalence of 0.31 ± 0.06% and an XT

prevalence of 1.25 ± 0.28%. The non-gold standard studies we compiled for East Asians (n=37) had an ET prevalence of 0.31 ± 0.04%, and an XT prevalence of 1.16 ± 0.17%. There was no statistically significant difference between the two types of studies (Student's t-test, in both cases p > 0.40).

For Middle Eastern (non-Persian) Populations, Sharbini (2015)[A] identified four "gold standard" studies,[16,89,256,457] with an ET prevalence of 0.96 ± 0.35% and an XT prevalence of 0.44 ± 0.20%. The non-gold standard studies for Middle Eastern populations (n=7) had an ET prevalence of 1.08 ± 0.15%, and an XT prevalence of 1.01 ± 0.36%. Like the other ethnicities tested, we found no statistically significant difference between the two types of studies (Student's t-test, in both cases p > 0.10).

For all other ethnicities (Africans, South Asians, Latinos/Hispanics and Native Americans), there are either too few "gold standard" studies or too few control studies to allow formal statistical analyses (in all cases n≤3). Nevertheless, based on the three ethnicities where such an analysis was possible, we conclude that there is no significant difference between gold standard and non-gold standard studies, and therefore one should not restrict analyses exclusively to so-called gold standard studies.

ii. Potential Sampling Biases: Neglect of subjects with major disabilities. One potential problem of prevalence studies (as explained in section 2.5.2) is the concern that children with major disabilities may be missed in school-based studies, because they attend special schools or no schools at all, resulting in an undercount of strabismus cases. This bias is not present in birth-cohort studies where all children are tracked. When we compared the strabismus prevalence in birth-cohort studies in Caucasians (n=13),[65,147,287,394,420,428,491,575,624,649,732,748,833] with otherwise comparable school-based studies, there was indeed a 15% higher prevalence in the birth-cohort studies (data not shown), suggesting that about 20 million children worldwide may be missed in estimates derived from school-based studies. Such numbers are supported by studies that included subjects from schools for disabled children[187,251] and by recent estimates of the global number of strabismic children with cerebral palsy[333] or Down syndrome.[808] These are

just two of the many disabilities that may prevent normal school attendance. Accordingly, current estimates of the global number of strabismus cases may be too low by 15%.

iii. Bias in Very Large Cohort Studies? In general, studies with the largest cohorts are considered the most reliable for clinical trials, while those with very small cohorts are more likely to generate outliers.[751] However, we noticed that in some of the ethnicities (South Asians, Caucasians, African Americans), the largest cohort studies reported a strabismus prevalence that was significantly lower than the pooled prevalence estimate. For example, total horizontal strabismus in South Asians in Southeast India was 0.26% according to the three largest cohort studies,[177,400,733] while the pooled estimate was 0.90%, a significant difference (p=0.02). Likewise, the largest cohort studies in Europe[343,599] and North America[200] reported 2.15%, 1.29%, and 2.07% horizontal strabismus for Caucasians, while the pooled estimates for Caucasians in Europe and North America were 2.69% and 2.49%, respectively, again a significant difference (p=0.008), and similarly for African Americans where Traboulsi et al.[781] reported 2.1%, while the pooled estimate was 2.61%. Therefore, unlike most other types of clinical studies,[751] in prevalence studies of horizontal strabismus, the largest cohorts may not necessarily provide the most reliable results.

iv. Potential Publication Bias and Meta-Analysis Bias: Analysis of Funnel Plots. Since one needs a sufficient number of studies to interpret funnel plots,[440] we focused on Caucasians and East Asians – the ethnicities with the largest numbers of studies. We first plotted the data from Caucasians in Europe for ET prevalence in a funnel plot (Fig. 9A). The plot shows a fairly symmetric distribution around the pooled estimate of 2.1%. There was no major or obvious lack of data points in the funnel, indicating that publication bias was minimal. When we plotted the data from East Asians for XT prevalence (Fig. 9B), we noticed an anomaly: there were groups of data points with abnormally high prevalences that had in common that they were published in 2014 to 2021, from China[142,144,261,325,456,604,822,864,866] and from Nepal.[607,725] These eleven studies showed a much higher prevalence for XT than those of the previous two generations (Fig. 10B, see section 3.12). The recent studies from China and Nepal apparently form a separate sub-

group that requires exclusion from the original funnel plot (Fig. 9B).[752] Consequently, the funnel plot showed that XT prevalence in China's current generation differs from previous generations, and that this trend is not shared by other East Asian countries except for Nepal (see next section).

3.12 Generational Changes in Frequencies and Prevalences of ET and XT

According to clinic-based studies that used longitudinal designs (medical records of clinic visits and surgeries performed in Europe, Canada, USA, Israel, Japan and China), the frequency of ET surgeries has been declining for several decades (from the 1970s to the early 2000s), in some regions by more than 50%,[62,126,158,236,253,332,366,464,596,663,719,824] while in other regions, especially in East Asia, the frequency of XT diagnoses or surgeries appears to have been increasing.[149-150,376,433,448,498,720,824,855,857] It has remained unclear whether these trends over decades are due to changes in prevalence of ET, to changes in prevalence of XT, simultaneous changes (but in opposite directions) in both ET and XT prevalences, or whether they are due to other parameters, such as changes in patient behavior, changes in effectiveness of screenings and/or treatments.[62,720,B] To answer the question about changes of prevalences over time, we compared prevalences in ethnicities with longitudinal data from population-based studies.

i. In Caucasians within Europe, the prevalence of XT gradually increased over the last 2-3 generations (Fig. 10A). The prevalence of ET was stable from the 1860s to 1935, nearly doubled in the generations of 1935-1995, and then decreased back to base levels in the current generation (1996-2025) (Fig. 10A). The number of studies for the period of 1846 to 1935 is relatively sparse, but the ET prevalence of approximately 1.5% to 2.2% is supported by several studies from the UK that did not meet our inclusion criteria because they reported total horizontal strabismus and/or ET/XT ratios for different cohorts.[VV] Accordingly, there appears to have been an epidemic of ET in Caucasians in Europe between 1935 and 1995, particularly pronounced in the 1950s and 1960s. The ET prevalence then stabilized between the 1990s and 2025 in Caucasians.[332]

ii. In East Asians, ET prevalence does not differ significantly between generations, but in the Chinese and Nepalis, XT prevalence increased dramatically from 1996-2010 to the

subsequent period of 2011-2025 (Fig. 10B), suggesting a current XT epidemic among Chinese and Nepalis. In East Asians other than Chinese and Nepalis, the increase in XT prevalence was much more gradual and appears to have stabilized between 1980 and 2025 (Fig. 10A).[426] Strabismus surgeries already increased in China prior to 2014,[376,377,448] but there was an acceleration with large increases from 2016 to 2019 (and a COVID-related decrease in 2020).[102,819] Possible reasons for these two epidemics will be discussed in section 4.2.

3.13 Use of Ethnicity-Weighted Contributions for the Estimation of the Global Prevalence of ET and XT

Previous studies have quoted a large range for prevalences of horizontal strabismus, between 0.13% and 9.9% (compiled in Table 1, illustrated in Fig. 1). Generally, the global prevalence is thought to be about 2-4%, but most of these ranges did not take into account ethnic differences or differences between generations. We prepared estimates of the global prevalence of ET and XT – using the cohort-size adjusted % prevalence – by weighing populations (ethnicities) according to their contribution to the world population as published by the United Nations.[H] We could calculate generational changes for only two ethnicities, Caucasians and East Asians, because there were not enough studies to reliably detect secular differences in other ethnicities. For this reason, only Caucasians and East Asians were assessed differentially for the previous and the current generation, while the prevalences for the other ethnicities are only adjusted for population growth, but we do not distinguish between two different generations – basically assuming no change (Tables 4, 5).

     In the previous generation (1965 to 1995), we estimate that 86.5 million people in the world had horizontal strabismus, 50.5 million with ET, and 36.0 million with XT. This results in a global ET prevalence of 0.96%, and a global XT prevalence of 0.69% for the previous generation (Table 4). The ET prevalence was 3.0% in Caucasians in Europe and 1.8% in Caucasians outside of Euope. In East Asians, the XT prevalence was 0.6%. Due to the higher prevalence of ET in Caucasians (peak of the ET epidemic), but the not yet increased XT

prevalence of East Asians (still at 0.6%), the global prevalence of horizontal strabismus was slightly lower (at 1.64%) in the previous generation than it is today (1.81%).

In the *current generation* (1996 to 2025), we estimate that a total of 138.5 million people have horizontal strabismus worldwide, with 51 million having ET, and 87.5 million having XT (Table 5). This results in a global prevalence of horizontal strabismus of 1.81%, with ET at 0.67%, and XT prevalence at 1.14% in the current generation. Thus, compared to the previous generation the ET prevalence decreased, but the XT prevalence increased substantially, due to the decrease in ET in Caucasians, and the large increase of XT in East Asians (mostly in China). For these estimates, we did not take into account the bias caused by neglect of children with major disabilities (revealed by comparison with birth-cohort studies), and this prevalence estimate therefore may be an underestimate.

4 Discussion

In the discussion of our findings, we first review potential sources of bias when estimating prevalences, and then comment on the ethnic patterns of horizontal strabismus, many of which are reported here for the first time. We also review the history of the discovery of ethnic variations in strabismus, including why most of these patterns have eluded recognition for many decades. We discuss implications for understanding how such remarkably robust patterns evolved, apparently through emergence of divergent gene pools due to gene admixtures and human migrations. Finally, we present a new theoretical model of how intrinsic factors (genetics) determine a disposition for horizontal strabismus types, but this disposition can be modified by extrinsic risk factors.

4.1 Technical Considerations: Sources of Bias in Prevalence Studies

Previous investigators have recognized some of the types and sources of potential biases that need to be considered when attempts are made to estimate the prevalence of horizontal strabismus. Such potential biases include the following: methodology used for examination, classification of strabismus types, study design with possibly biased sampling, age of cohorts, effects of socioeconomic status, geography (latitude), and ethnicity.

Different *methodology* may be used in different studies for sampling, screening and examination,[23,61,174,293,356,395,A] and different *terminology* may be used to describe and sort the results,[261,287,583,697] different studies may apply varying definitions of manifest strabismus (strabismus angle), and some may have included microstrabismus[491] or convergence insufficiency.[345,352,465,697] During screening, different types of *diagnostic measures* may be used, and small deviations or intermittent *types of strabismus may be missed*,[142,149,200,255,286,303,421,604,631,697] or may be deliberately excluded.[18] Some children are too young to cooperate during examination.[399,604] Depending on the screening design, some studies may have *low (parental) response rates*.[453,491,501,545,582-583,666,A,W] Some studies excluded subjects

whose strabismus had already been treated,[200,201,255,261,417,J] and school-based studies may miss those children who are unable, due to *disabilities*, to attend normal schools or preschools and child care centers.[110,113,122,255,333,369,575,582,808,A] Such an underrepresentation of children with disabilities is a concern, because children with disabilities are known to have substantially increased prevalences of ET and XT.[39,159,223,251,295,312,333,515,745,783,808,813,818,836] Another potential source of bias regarding sampling is that some populations, due to differences in cultural beliefs, may hide people with ET or XT from investigators so they may be excluded from surveys, while other populations may try to find especially those subjects with ocular misalignments,[280,482] either of which may introduce bias. Cohorts of different *ages* were examined (Fig. 6), and studies examined populations of different *ethnicities*.

Additional concerns are publication bias, because data not supporting the predominant notion of a 2-4% prevalence of horizontal strabismus may not be submitted or accepted for publication. This is a particular concern for studies in countries where the prevalence of horizontal strabismus apparently is lower (Africa, South Asia) than in other regions, or where the type of strabismus pattern differs from the Caucasian "norm", as is the case in East Asia, West Africa, and in Persians (Fig. 3; Supplemental Table S1).[41,290,341,419,554,641,846] Since authors usually compare their results with previously published studies, they may have doubts about the validity of their results and therefore may be more hesitant to publish seemingly discrepant results.

4 2. Measurement, Evaluation and Minimization of Biases

We here discuss how we quantifed and, when relevant, controlled for effects of age, latitude, ethnicity, method of sampling, and publication bias in the estimation of prevalence of horizontal strabismus.

Age: We identified age as an unlikely factor for explaining differences in prevalences between ethnicities. Studies of different ethnicities overall mostly examine children of similar ages (see Fig. 6A-F). While age clearly has an effect on prevalence, it does not explain the distinct ethnic patterns. Several studies reported that Caucasian patients "grow out of ET in or after puberty" – likely due to a widening of the interpupillary distance and growth-related

changes of the orbital angles around the time of puberty, thereby reducing the disposition and risk for ET.[572,603,605,771,810,815,826-827,862] Another – trivial – explanation for the decreased prevalence of horizontal strabismus in adults may be that in a significant fraction of cases the misalignment was corrected by surgery or by botulinum toxin treatment, although nationwide studies suggest that only about 2% to 5% of strabismus cases actually are treated with surgery.[165,451,660,663] When we compared studies on older adults with studies on younger adults, XT prevalence or frequency was higher in the older adults, and this was apparent in both population-based and clinic-based studies, and in diverse ethnicities, including Caucasians,[178,218,231,251,356,469,658,D] African Americans,[D] East Asians,[282] Hispanics/Latinos,[671] and Persians.[320] The shift towards XT in older age likely is due to age-related fat absorption in the orbit which causes a decrease in propotosis, which increases the risk for XT.[31,67,862]

Latitude: We quantified the effect size of latitude for the ET/XT ratio independent of ethnicity and found it to have no effect. The coefficient of determination (R^2) was 0.003-0.004 – insignificant when compared with the effect size of the width of the orbit in different ethnicities.[862] We conclude that latitude has no effect on horizontal strabismus. In this context it should be noted that an alternative, more plausible explanation for increased XT in Caucasians residing in regions such as South Africa and Australia has been proposed: the process of emigration will select families with a tendency to XT.[357]

Ethnicities: The distinct patterns of horizontal strabismus in the major ethnicities have not previously been appreciated – this is the main novel finding of our systematic review. Our comprehensive quantitative analysis and comparison of multiple ethnicities provide a wealth of new insights, detailed in sections 4.3 and 4.5, below. Our findings allow us to predict prevalences, recognize trends, and allow us to dissect the contributions of intrinsic and extrinsic risk factors that may differ between regions and at different epochs.

Lack of Data for Some Countries or Populations – Gaps in Knowledge Base: We identified for which countries ET and XT information appears to be lacking – see Fig. 4, our world map. In addition, we identify which populations, countries and continents are under-represented in data on strabismus prevalence, and we point out which populations should be

prioritized for gaining a better understanding of true prevalences and for providing a more reliable global estimate. There are relatively few studies from certain regions in South America, South Asia, Africa, and Central Asia.

Effect of Methodology/Sampling/Study Design: We addressed this issue and roughly quantified its effect. We compared Sharbini's (2015)[A] so-called gold standard studies (conducted by "experts") with the results obtained by comparable studies with the same ethnicity, and we conclude that these potential biases are small, as they were not statistically significant. When we quantified the potential bias due to *disabled children not attending normal schools*, by comparing birth-cohort studies with relevant school-based studies, we found a surprisingly large difference – indicating that as many as 15% of cases with strabismus may be missed (section 3.11.ii). This suggests that there is a substantial sampling bias, consistent with recent conclusions.[333,808] Some of the studies with the largest cohorts were found to report a lower strabismus prevalence than the pooled strabismus estimate, possibly because reduced time was expended for examining each subject,[496] and therefore some forms of strabismus may have been missed (sections 3.11.iii and 4.1).

Because of the possibility of missing intermittent types of strabismus, under-reporting of some treated cases, and missing some children who cannot attend normal schools, we consider our prevalence estimates to be at the lower end, and the true prevalence may be somewhat higher, possibly requiring an adjustment of current estimates, although this must be confirmed in non-Caucasian ethnicities. Nevertheless, it is now possible to estimate ET and XT prevalences globally, and for individual countries, as long as their ethnic make-up is known – even when there are no empirical studies yet that have been performed in those particular countries.

4.3. Comparison of Results obtained from Population-based and Clinic-based Studies

Regarding the epidemiology of strabismus, two main types of studies must be distinguished:[390] community- or population-based vs. clinic-based (patients presenting at, or being referred to, clinics). Many investigators are aware of the difference in the types of conclusions that can be drawn from population-based vs. clinic-based

studies.[135,149,170,173,207,219,282,390,455,473,575,748,773,778,811,841,857,868,A] Some investigators[753] have stated that clinic-based studies appeared to yield results that are similar to those of population-based studies, especially for the collection and analysis of data regarding the ET/XT ratio. Clinic-based studies have also been justified as being "more consistent and reliable."[174] Others have cautioned that these two types of studies can not be directly compared,[149,179,390,473,841] and, indeed, comparison of six clinic-based studies with five population-based studies, all on Caucasians, has shown significant differences (more than three-fold) in the ET/XT ratio between clinic-based and population-based studies (16.6 vs 4.7),[179] yet it has remained unclear by how much the ET/XT ratio differs between clinic-based data and data obtained from the general population. Our meta-analysis allows us to quantify the effect size and to determine whether such bias is present only in some ethnicities or whether it is present similarly in all major ethnicities. We show that this bias in clinic-based studies is considerable, overall about 14%, although it varies in size between ethnicities and is smaller in populations with large fractions of ET (Fig. 7). We conclude that clinic-based studies underestimate the relative frequency of XT versus ET. This has important consequences when clinic-based data are used to estimate relative frequencies of ET and XT, e.g., in countries lacking population-based studies (Fig. 4).

The reasons for the reduced appearance (or frequency) of XT in the clinic are not known, but may be a reflection of the fact that XT often starts with an intermittent course,[370,562,586,810] although others disagree.[672,697] Such intermittent appearance of symptoms may result in less urgency, by the patient, to consult with a clinician. Forms of strabismus such as intermittent XT may be tolerated by the child and his or her parents more readily and therefore the subject may not seek medical attention.[69,149,173,255,382,646,773,778,841] ET causes amblyopia more often than XT does.[170,666,735,850] This may also be a cause for delay in XT treatment, because the ophthalmologist may be less inclined to initiate treatment,[158,288,434,672,697,749] but there is some disagreement.[83,854] Furthermore, because clinic visits are more cumbersome for people living in the countryside (patients must travel larger distances), clinic-based studies may miss cases in rural populations.[646] This would lead to an underestimate of horizontal strabismus, and possibly affect XT more than ET.

4.4. The Role of Socioeconomic Status (SES) vs. Ethnicity

Studies have reported inconsistent results regarding the question whether SES contributes to ET or XT prevalence, as detailed in Section 3.10. Ethnicity can be strongly associated with SES,[834] but the predominant effect of ethnicity on horizontal strabismus was not appreciated until recently. The correlation of SES with ET or XT in some studies may have been due to ethnic differences: i.e., there could have been biological rather than socio-economic reasons for the differences in strabismus prevalence. Biological differences between ethnicities can be mis-interpreted as differences in access to health care – "health disparities," and vice versa. When fewer cases of strabismus are diagnosed or treated in a population, this can be due to health disparities, but, in the case of Hispanics/Latinos, Africans and some Asian ethnicities, it may be mostly or entirely explained by biological differences between ethnicities rather than being due to health disparities/access to care, as has been frequently assumed.[162,210,244,269,396,450,658,812,853,WW]

Another, "simple," explanation has been offered to explain an association of lower SES with strabismus: it has been reported that parents of the upper class more swiftly recognize eye deviations in their children, and they have the time and means to procure prompt clinical attention and treatment.[771] Regarding the reason for an association between low SES and strabismus, it was commented that "children [from a lower social class] are more difficult to treat effectively rather than that they more commonly develop strabismus",[287,746] which is in addition to possible health disparities[210] and compliance issues for children with a low SES.[92,632,740,810] Future studies on strabismus will have to take into account ethnicity as a confounding variable when assessing effects of SES.

4.5. Global Distribution of Horizontal Strabismus – Ethnic Patterns

The most intriguing finding of our study is the emergence of surprisingly distinct and consistent ethnic patterns in the prevalences of ET and XT. We show that ethnic differences and prevalence patterns affect many more populations and are much more robust than was

previously realized. These findings are important for several reasons: First, they show that a global prevalence can only be established when ethnic differences are taken into consideration and weighed appropriately. In order to estimate strabismus prevalence within a population, the ethnic make-up of the population needs to be known. Second, to interpret trends, one must compare differences and trends *within* ethnicities, not between ethnicities – this is necessary to recognize changes in strabismus prevalence between generations. When prevalences are compiled globally or compared between different ethnicities, existing trends may be diluted or cancel out and therefore may become invisible. Third, the underlying mechanism appears to be variation in the orbital anatomy (and thus genetics),[341,815,862] indicating an intrinsic disposition for horizontal strabismus prevalences and patterns that can be modified by extrinsic risk factors (such as maternal smoking, premature birth, Cesarean section, refractive error). Fourth, ethnic differences in strabismus are important clinically and from a public health perspective because of different frequencies of co-morbidities (e.g., amblyopia, mental health). Ethnic differences need to be taken into account to identify true health disparities, and to adequately plan for care of strabismus in the future.[659,857] Such care needs to be tailored to the needs of local populations, but also to prepare adequately for sequelae such as increased mental health issues, especially increased schizophrenia, that may follow increased XT rates decades later.[27,507,780] Finally, for the first time, total numbers of esotropes and exotropes regionally and worldwide can be estimated, and prevalence changes tracked longitudinally – opening new avenues for assessing roles of major known risk factors for horizontal strabismus which may differ between regions and ethnicities (see sections 4.8 and 4.9).

Some ethnicities (Africans, South Asians, indigenous people in Oceania) have much lower overall strabismus prevalences than the other major ethnicities (Fig. 3). Two possible reasons for this difference, not mutually exclusive, must be considered. First, some populations may have a low kurtosis in the anatomical parameters that impact on strabismus disposition: Interpupillary distance, proptosis and orbital angle. If some populations have fewer extremes in these orbital parameters, then there will be fewer individuals at risk, resulting in lower prevalences. Second, it is possible that babies or children with disabilities (e.g., low birth weight,

premature birth, hypoxia during birth – which makes them higher risk for strabismus) do not survive in societies with less advanced health care systems, and this would reduce the ultimate strabismus prevalence in the population.[80,317,333,815] If the second reason is true, then one would expect that, as health care facilities improve in developing countries, the prevalence of horizontal strabismus increases. Based on the currently available data, there do not seem to be such trends (yet). Of course, changes in multiple risk factors for strabismus play a role, making it difficult to adequately explore this possibility.

4.6. Ethnic Differences in ET and XT Prevalences: Evolutionary Implications

Our quantitative summary (Fig. 3) and the world map (Fig. 4) show notable differences in prevalences between ethnicities. Populations residing in regions with frequent migrations and/or frequent gene admixture in historic and prehistoric times (Middle East, Mediterranean, North and West Africa, Northwest India, Latin America)[593] tend to have intermediate ratios of ET/XT prevalence, while those populations that have been more isolated (remote), or in extreme locations with less opportunity of gene admixture, have more extreme ET/XT patterns (Western Europeans, Native Americans, East Asians, indigenous people of Australia, Eskimos/Inuit). Northwestern Europe was considered a geographical "cul de sac" in terms of ancient human migrations.[608,765] The distribution of ethnic strabismus prevalences and ratios provides strong clues of how such patterns likely have evolved. Essentially, to permanently alter the ET/XT patterns within a population, admixture between populations has to happen. Several studies have shown that admixture between ethnicities leads to intermediate ratios and patterns of ET/XT,[361-362,517,FF] with other examples showing that ET-XT-related parameters such as interpupillary distance and interorbital width also become intermediate in ethnically admixed offspring.[245,334] This leads to intriguing questions of how the ethnic ET, XT diversity originated in anatomically modern humans – possibly due to gene admixture when anatomically modern humans encountered and interbred with archaic hominins[111,276,524,592,593,798,803] who had a wider orbital width (Neanderthals and Denisovans).[524,614,XX] A wider orbital width associates with increased inclination towards XT.[406,675,862] Current patterns of ET/XT ratios in different countries

and ethnicities are not only compatible with conclusions from population genetics, but they are best understood in the context of ancient human gene pools, gene admixture between populations, and ancient and more recent human migrations.

4.7. History of the Discovery of Ethnic Patterns

Given the distinct differences in strabismus patterns between ethnicities, it may appear surprising that most of these patterns have remained undetected for so long. In this section, we will examine the reasons for this delay. There seems to be a combination of factors responsible, including: Small number of studies for many ethnicities, neglect of key existing studies by researchers, and variability of results. There has been a considerable focus on Caucasians and neglect of other ethnicities, especially prior to the 1950s. Some key early studies, e.g., on African Americans, Africans, and East Asians were overlooked, apparently because they were not published in mainstream journals,[285] or were published in non-English languages.[341,554,FF] Additionally, many investigators were unaware of the importance of reporting data separately for different ethnicities.[841] The African patterns remained hidden, despite first reports, more than 80 years ago, of prevalences in Africans that differed from those in Caucasians.[341] Asian patterns remained unknown to most investigators despite multiple studies in the 1950s and 1960s[473,554,555,G] – reviewed in 1972[419] – apparently because most of them were published locally in non-English journals. Mosaic patterns such as those in Africa, the Arctic, the Middle East, or South Asia were difficult to discern early on, when data from only a handful of studies were available.

i. Africans and African Americans. It was noted at the beginning of the last century that Africans and African Americans "rarely, if at all" have strabismus[114,120,418,431,523,616] – reviewed by multiple authors.[19,341,696,815] However, these initial reports were merely anecdotal impressions suggesting that some Africans have a lower prevalence of strabismus than Caucasians, and other investigators emphasized that strabismus does exist in Africans.[14,183,341,418,815] The first systematic, population-based studies were conducted by Holm[341] in Africa, and by Gover and

Yaukey[285] in the USA, and both revealed a low prevalence of horizontal strabismus among Africans and African Americans. However, the study in the USA[285] is often overlooked: For example, Hansen (1971)[313] says, incorrectly, that "no information is available on the comparative occurrence of strabismus in blacks and whites in the United States." The lower prevalence of horizontal strabismus in West Africans[341] was confirmed by additional studies (Supplemental Table S1).[15,86,335] Some practitioners took issue with the statement "squints are extremely rare in coloured races" (Squint Editorial in the British Medical Journal)[746] – Taylor[766] countered that "squints are very common in East Africa." Indeed, several population-based studies from East Africa confirmed relatively high prevalences (e.g., Kenya: 2.86%,[R] Ethiopia: 3.1% and 4.4%,[242,838] Sudan: 2.73%).[760] Yet, overall, most studies agree on a lower strabismus prevalence, and especially a low prevalence of ET, in Africans and African Americans when compared with Caucasians.[80,162,174,252,313,341,396,815,843,S]

Besides the issue of a low overall prevalence of horizontal strabismus among Africans and African Americans, there is a second parameter of interest: the ET/XT ratio. The ET/XT ratio was initially reported to be very low in Africans,[341] and this was supported by subsequent studies in Africa,[15,33,76,225,335,423,843,R,S] and two studies in the USA.[545,D] Some authors state that Gover and Yaukey[285] were the first to report that XT is more frequent than ET in African Americans.[220,612,696] This is incorrect and due to a misread of Schlossman and Priestley's review[696] by Abrahamsson et al.[19] Roberts and Rowland[D] and the Multi-ethnic Pediatric Eye Disease Study Group[545] were the first to report a greater XT than ET prevalence in African Americans. However, other studies in Africa, and most of the ones in the USA, reported approximately equal ratios of ET and XT (USA and Caribbean,[170,187,255,632] Africa,[252] or even higher ET than XT prevalences (USA,[147,259,631] Africa,[49,71,86,103,275,551,760]). How can such seemingly discrepant results be explained? Two possible, not mutually exclusive, explanations are (1) that the ancestors of current day African Americans have admixed with Caucasians to dilute the original pattern (indeed African Americans have, on average, only 70-80% original African genes,[84,115-116]) and (2) the ancestries within in Africa are not uniform, but constitute a mosaic of patterns.

Our study is the first to show that there are indeed two major patterns of horizontal strabismus in Africa. Many of the early studies happened to examine Niger-Congo-Bantu populations in West Africa, where in general XT prevalence exceeds ET prevalence (Fig. 4; Supplemental Table S1). Friedman et al.[255] suggested that ET/XT differences between cohorts of African Americans may reflect the fact that they originated from different sites and populations in Africa and thus reflect genetic differences – a notion which our review and other studies support.[84,115-116,121,167,774] Indeed, a smaller fraction of African Americans has origins among the Niger-Congo-Bantu in West Africa, while the majority of African Americans appears to originate from other populations in Africa.[115] With additional reports from the last 12 years, significant ET/XT differences between Niger-Congo-Bantu and non-Niger-Congo-Bantu populations have now emerged – this mosaic pattern on the African continent would have been difficult if not impossible to recognize just one or two decades ago due to the scarcity of studies (Fig. 4; Supplemental Table S1).

ii. East Asians. East Asians are known to have a higher XT than ET prevalence. Such differences, when compared with Caucasians, were first documented for the Japanese in 1954,[554] and for Chinese living in Fiji.[G] These initial reports were supported by subsequent studies in the 1950s, 1960s, and 1970s in Japan;[314,473,493,517,555,584,844,FF] – for a review of the early literature, see Konyama, 1972.[419] This divergent pattern – East Asians having patterns distinct from Caucasians – was further confirmed in the 1970s, 1980s and 1990s in Thais,[419,470] in Koreans,[639,856] in Malaysians,[769] and eventually in Chinese populations (Taiwan,[449,705,821] Hong Kong,[206] Kazakhstan,[375]). However, none of these studies attracted much attention, and therefore the difference between East Asians and Caucasians regarding the ET/XT ratio remained hidden. The ethnic difference was effectively communicated to a wider audience only relatively recently, by Yu et al., 2002,[857] based on clinic data.[433]

Some articles and reviews, including recent ones, group all "Asians" in the XT >> ET category,[220,282,290,317,318,442,615,855] however, our work shows that this is incorrect, because a sizeable fraction of South Asian populations does not share the East Asian pattern. To our

knowledge, the difference in strabismus patterns between populations in the Northwest and the Southeast of the Indian subcontinent has not previously been noticed (see below, section 4.5.vi).

iii. Pacific Islanders. The work of early investigators[216,482,484,486,802,G,X] showed that the indigenous people in the South Pacific (including Australia) generally have very low prevalences of strabismus, and an especially low, almost non-existing prevalence of ET. This was confirmed by more recent studies.[345,590,767] Mann[482] realized that the global variation of horizontal strabismus was primarily due to differences in the prevalence of ET, not in the prevalence of XT.

iv. Native Americans. Initially, the strabismus pattern of Native Americans was difficult to recognize. Apparently, none of the authors conducting studies in North America[25,152,271,437,489,830] were aware of reports from South America,[99,790] and one of the first studies in North America combined data from Eskimos/Inuit and Native Americans,[841] thus "diluting" the diametrical patterns of these two ethnicities. The recent study from Brazil by Germano et al.[272] was not aware of the earlier Latin American literature on Native Americans.[99,483,517,790,FF] When one considers all available studies, including the more recent ones from the last 20 years,[152,271,272,437] together with some of the classic older studies,[25,99,489,517,830,790,FF] it emerges that Native Americans, overall, have less horizontal strabismus than Caucasians,[853] and that their pattern (with significantly more XT than ET) is remarkably similar to that of East Asians (Fig. 3). The finding of a lower prevalence of strabismus in Native Americans is supported by qualitative observations such as "no Indians … ever get concomitant strabismus unless white blood is present"[129] and "Indians have less muscular problems [than Caucasians]."[309]

v. Eskimos/Inuit. Ida Mann emphasized the high frequency of ET in Eskimos/Inuit based on clinical cohorts,[486] but a subsequent population-based study in Canada reported only on the combined data from Eskimos/Inuit and Native Americans.[841] This obscured the distinct pattern in Eskimos/Inuit. A high ET prevalence among Eskimos, as reported by Mann in 1972,[486] was

corroborated.[380,835] Apparently unaware of Mann's and Wyatt and Boyd's work,[486,841] Woodruff and Samek[835] commented on the fact that the frequent ET in Eskimos/Inuit was not due to hypermetropia; they found "no reasonable explanation of cause" for the frequent ET in Eskimos/Inuit. Apparently, the authors missed the works of Skeller (1954)[736] and Waardenburg (1954)[815] who had pointed out a narrow interorbital width and a particularly short interpupillary distance that is unique to the Eskimo/Inuit skull,[125,353] thus providing a plausible explanation for the frequent ET in Eskimos/Inuit.[815,862]

vi. South Asians. The first population-based studies from South Asia generated a confusing picture, since the studies from the Northwest of India indicated an ET/XT ratio that was approximately equal or showed much more ET than XT,[26,296,546] while population-based studies from Southeast India indicated a much larger prevalence of XT than ET.[427,652] Nearly all subsequent studies from the Northwest of the Indian subcontinent confirmed a similar prevalence of ET and XT or more ET than XT,[94,530,716] with only one study showing significantly more XT than ET.[72] In the Southeast of India, nearly all studies report a much lower ET/XT ratio.[29,68,176,300,393,400,552,688,733] Despite the relatively sparse number of population-based studies in South Asia,[861] thus, the evidence for differences between these populations is accumulating. Accordingly, there is no single "South Asian" pattern, because the pattern in Northwest India and in Pakistan is more similar to that of most populations in the Middle East, which differs significantly from that of East Asians, while South Indians' and Persians' patterns may reflect their common Dravidian ancestry.[91,232,383,475,655]

vii. Middle East. The first studies from the Middle East were on Jews and Arabs, with later studies on Turks and Persians. It turned out that prevalences from countries with Jews, Arabs, Turks and Kurds were very similar, with ET typically exceeding XT prevalences, similar to Caucasians and North Africans, while Persians consistently show a higher prevalence of XT over ET, more similar to Southeast Indians and East Asians. Insights into differences among Middle Eastern populations were made possible only in the last decade, since countries such as

Iran do not seem to have any population-based studies in the 20th century that distinguished between ET and XT (Supplemental Table S1).[318,403,679]

In summary, recognition of differences between ethnicities and patterns of strabismus prevalence requires adequate numbers of population-based studies, and for many countries and populations, such studies have become available only in recent years. Some insights into ethnic differences remained hidden due to neglect of reports published in languages other than English. As with a giant jig saw puzzle, a sufficient number of prominently placed pieces of the puzzle is needed to recognize patterns, and initially, these pieces were too few and too far between. However, clear patterns are now emerging that not only provide a convincing account of the current status, but also intriguing indications on how these distinct patterns of strabismus prevalence must have evolved.

The basis and mechanism of the ethnic strabismus patterns likely relate to the known differences between ethnicities in orbital anatomy: interorbital width, interpupillary distances, and proptosis.[86,104,341,406,431,487,517,633,635,756-757,815,862,FF] Such differences between ethnic groups shift the balance between enhanced disposition (risks) for ET vs. XT.[406,431,815,857] This notion is supported by the well-known fact that clinical syndromes with narrow interpupillary distances (e.g. Down syndrome) have much more ET,[336,368,808] while syndromes with extremely wide interpupillary distances (e.g., Crouzon or Apert syndrome) have much more XT associated.[675] In addition to orbital parameters, the potential role of refractive errors needs to be considered. Numerous studies have shown associations between refractive errors (hyperopia, myopia, astigmatism and anisometropia) and different types of horizontal strabismus.[170,444,764,866] Esotropia is associated with hyperopia, and exotropia is associated with myopia. However, the causal relationship between refractive error and strabismus is unclear, and it has been suggested that exotropia may cause or worsen myopia rather than the refractive error causing the strabismus.[211,866] Since the prevalence and types of refractive error differ between ethnicities, it is tempting to speculate whether the current myopia epidemic may, in part, explain the recent XT surge in China. However, the fact that the myopia epidemic involves all of East

Asia, including Korea, Japan, and Indonesia,[801] but the XT surge is only seen in China (and Nepal), indicates that other factors must play a role.

It goes beyond the scope of our review to discuss the extensive literature on refractive errors and strabismus, or the above-mentioned craniofacial dysostosis syndromes, or the evolutionary history of diverse orbital patterns in different archaic and modern human populations, or to discuss the probable molecular and genetic bases of orbital diversity – which all are fascinating topics for further study.

4.8. The Global Prevalence of Horizontal Strabismus: Intrinsic Factors, Extrinsic Factors, and Generational Changes

Estimation of the global prevalence of horizontal strabismus is challenging because the global prevalence is composed of the sum of all the ethnically distinct prevalences among its constituent populations. Furthermore, the ethnically distinct prevalences are determined by two types of factors: (1) intrinsic (genetic) factors that govern the shape of the orbit, and (2) extrinsic factors that impact on the anatomically defined intrinsic "baseline." The occurrence of two epidemics, in populations (Europeans and Chinese) whose ethnic make-up has changed minimally, if at all, suggests that the intrinsic, genetically determined disposition for horizontal strabismus can be modified by extrinsic (environmental) factors. The relevance of extrinsic factors becomes apparent when one analyzes generational changes of strabismus prevalence within the same population. The most likely relevant extrinsic factors (risk factors) are cultural and health factors such as maternal smoking and Cesarean section,[147,237,306,326,609,777,842,l] but there may be others: low birth weight (in Japan[762]) premature birth, some types of refractive errors, and reduced risks of childhood diseases due to vaccinations.[126,243] Both types of factors (intrinsic/genetic and extrinsic/environmental) need to be considered for the global prevalence. Some eye conditions have both intrinsic (genetic) and extrinsic (environmental) contributions, as exemplified by the phenomenon of myopia.[801]

Different estimates of global strabismus prevalence will be obtained when they are based on fractions of the world population that are not representative of the entire population, and different estimates will also be obtained when data from different generations are used for calculations, because exposure to extrinsic risk factors may differ between generations. In at least two major populations (Europeans and Chinese), strabismus prevalence has changed significantly between generations (Fig. 10A,B). For meaningful estimates and comparisons, it should be specified for which generation the prevalence is estimated.

Until now, many regional patterns of horizontal strabismus were not apparent, because differences between most ethnicities were not known, and because the changes in prevalence over time within the same population were not appreciated. Accordingly, postulated or assumed prevalences often were mixtures from different ethnicities, with contributing data from different epochs, sometimes going back several generations. Our meta-analysis with a global and historical focus makes possible meaningful analyses of both, global prevalence, and local prevalence, for different generations, and can reveal secular trends – for those ethnicities where sufficient numbers of studies are available. These new insights will allow investigators to determine with much greater precision the effects of known risk factors and to predict effects of such risk factors in current and future generations.

Our estimates of the global prevalence of ET and XT in the current generation, at 0.67% and 1.14%, respectively, are lower than those from some previous studies. Adinanto et al.[B] estimated horizontal strabismus at 2.9% in 2010-2015, while Hashemi et al.[318] estimated a 2.00% prevalence in 1986-2018, with 0.77% esotropia, and 1.23% exotropia. One major reason for the differences between estimates is that none of the previous studies accounted for the substantial ethnic differences, with very low prevalences in Africa and South Asia, and did not account for such effects on a global scale. Prevalences of past generations are not necessarily appropriate for estimating the *current* global prevalence, especially when current and past generations may have been exposed at different rates to extrinsic risk factors (such as maternal smoking, low birth weight, premature birth, Cesarean section).[101] The prevalence of ET in Europeans, with many studies from the peak of the ET epidemic, was taken to be representative

for other ethnicities, and this seems to be largely responsible for the broadly incorrect estimates of global strabismus prevalences as summarized in Table 1 and Figure 1.

4.9. Implications for Global Health beyond Ophthalmology

Strabismus has detrimental consequences not only for visual function such as possible amblyopia, loss of binocular vision and defects of stereopsis,[434,810] but also for psychosocial development[117,662] and development of mental illness, schizophrenia in particular.[27-28,379,445,507,511,535,560,698,780] The substantially increased risk of schizophrenia after childhood XT, and especially constant XT, is particularly concerning.[27,780,YY] Indeed, in countries such as China, where XT has been increasing in the last three decades, it has been reported that schizophrenia prevalence has more than doubled between 1990 and 2010.[134] Since XT prevalence has continued to increase in China, this trend and the delayed impact on schizophrenia, can be expected to continue for the next two decades, assuming that XT is indeed a significant risk factor for schizophrenia.[27] If true, then reducing modifiable risk factors for XT, such as Cesarean section[609,776] or certain types of refractive errors (severe myopia, astigmatism, anisometropia),[170,444,764,866] may decrease XT prevalence, and with that, eventually, schizophrenia prevalence. It is not known whether prompt treatment of XT may prevent schizophrenia from developing,[27,407] but this should be explored. Nevertheless, these considerations illustrate how important it is to know the prevalence of horizontal strabismus, to monitor trends, and to advocate preventative steps as well as early interventions in individuals with ET or XT.

5 Conclusions

Our work reveals that the preeminent factor that explains differences in prevalence of the different types of horizontal strabismus is ethnicity, rather than socioeconomic status, methodology, or geography. The underlying reasons for ethnic differences are likely due to

differences in orbital anatomy,[862] but this, and the effects of extrinsic (environmental) risk factors require additional investigation. We also show longitudinal, generational changes in strabismus prevalence. Monitoring strabismus prevalence between generations shows that extrinsic factors (risk factors) play a role, but their identification awaits future confirmation. With more accurate estimates of the global and local prevalence of esotropia and exotropia, and their trends, more targeted measures can be taken to mitigate the downstream consequences and adverse effects of horizontal strabismus on individuals and society. By facilitating access to a large body of previously neglected literature, our work provides a more appropriate context and comparison for future studies. This should stimulate further research to better understand horizontal strabismus and its evolutionary history.

6 Method of Literature Search

PubMed and Google Scholar were searched for relevant studies. Our review protocol was registered in PROSPERO (CRD420251080354).[E] The following search terms were used: "strabismus", "esotropia", "exotropia", "prevalence." Inclusion criteria were quantitative information on the prevalence of esotropia and exotropia or the ratio of esotropia/exotropia. There were no language restrictions as long as references or English titles or relevant key words appeared in searches. We accepted all studies that report original and quantitative data on frequencies of esotropia (ET) and exotropia (XT) in human subjects, either obtained from population-based surveys, or from medical records in clinical settings. Studies were included only when they provided *quantitative* information about both ET and XT separately (not just combined ET and XT prevalence or prevalence of horizontal plus vertical strabismus). We accepted both, population-based studies, as well as clinic-based studies (surveys of medical records from patients seeking attention at a clinic). Case reports were not included. All relevant studies were sorted into either population-based studies or clinic-based studies. Our search was

not restricted by year of publication or language. The last search was conducted on 1 July, 2025. For a detailed description of inclusion and exclusion criteria, quality and risk for bias assessment, data collection, and statistical analyses, please refer to the Methods section.

Key References

As key references, we selected Hermann Cohn, 1867 (Breslau, Germany),[163] because his was the first study reporting the prevalence of horizontal strabismus. We also include Stig Holm, 1939, (Lambarene, Gabon and Lund, Sweden)[341] because his work was the first to report on ethnic differences in the type and prevalence of horizontal strabismus. We acknowledge the pioneering work of Ida Mann, 1966, (Perth, Australia)[482] who provided the first global analysis and insight into ophthalmologic disease, including strabismus. The work of Emily Chew and colleagues (1994) (Bethesda, USA)[147] provided not only comprehensive data on strabismus prevalence, but also on extrinsic (risk) factors that modify strabismus prevalence. The final work that we acknowledge is by Hassan Hashemi and colleagues (2019) (Tehran, Iran),[318] because it was the first systematic review that estimated the global prevalence of strabismus, including esotropia and exotropia. All five works laid the foundation for significant progress in the epidemiology of strabismus and pioneered a better understanding of this disorder.

Disclosure

The authors have no conflicts of interest to declare, except that our study was supported by the National Institutes of Health, grant numbers EY031729 (C.S.v.B. and W.Y.) and GM103554 (C.S.v.B.).

Figure Captions

Fig. 1. Reports of ranges of strabismus prevalence according to the literature (1951 to 2019), compiled from Table 1, based on reviews and other reports[32,75,79,113,142,150,179,196,210,251,255,261,268,271,290,293,318,373,399,485,448,455,501,545,569,577,596,614.645,665,685,753,776,777,807,815, 817,845,86,A,B]

Fig. 2. Flow diagram of the search strategy, article selection, application of inclusion and exclusion criteria, and removal of duplicates. The literature search was last updated on July 1, 2025. This review protocol was registered in PROSPERO (CRD420251080354).[E]

Fig. 3. The graph shows the estimated random prevalence of esotropia (ET, blue) and exotropia (XT, red) for 13 different major ethnicities (all generations, when data are available) as indicated. Bars represent 95% confidence intervals, except for Eskimo/Inuit because n=2 for that ethnicity. Data were obtained from 295 population-based cohorts with subjects older than 2 years, and restricted to studies reporting distinct ethnicities. The numbers of studies and details about cohort sizes are summarized in Table 5. The data for Persians includes one study on Azerbaijanis. Abbreviations: E, East, N, North, S, South.

Fig. 4. World map of the esotropia/exotropia ratio (ET/XT ratio) among countries. These data were compiled from 295 population-based cohorts in 76 countries (Supplemental Table S1) and 360 clinic-based studies from 72 countries (Supplemental Table S2). ET prevalence much larger than XT prevalence (ET/XT ratio >1.5) is shown in blue; ET prevalence much smaller than XT (ET/XT ratio <0.67) is shown in red; ET similar to XT prevalence (ET/XT ratio of 0.67 – 1.5) is shown in yellow. The relative frequencies of ET and XT from clinic-based studies are indicated by light blue, pink, and light yellow, corresponding to the prevalence ratios and color scheme. For countries with multiple ethnicities, only ethnicity-specific data are shown. Note that ET predominates in countries with mostly Caucasian populations, while XT predominates in East Asia, Southeast India, West Africa and Persia. Sol. Islands, Solomon Islands. Map lines do not necessarily depict accepted national boundaries.

Fig. 5A-B. The graphs show that there is no association between the esotropia/exotropia (ET/XT) ratio and latitude. Panel A shows the data and flat trend line for Caucasians in Europe, panel B shows a flat trendline for East Asians. The coefficient of determination (R^2 values of 0.0003-0.0004) is indicated on the graphs.

Fig. 6A-F. The panels show the age ranges for each of the population-based studies compiled for the major ethnicities in Supplemental Table 1. The large majority of studies focused on the age range of 3-12 years when children have maximal prevalences of either esotropia (ET) or exotropia (XT), and this was confirmed by conducting the meta-analysis with and without the "adults only" studies. Studies in Latin America from regions with mostly Caucasian ancestry were not included in the panel D (Latinos/Hispanics).

Fig. 7A-B. The bar graphs compare the contribution of esotropia (ET) and exotropia (XT) to the total horizontal strabismus. A. overall (for all ethnicities, weighted by population size – see Table 3); and B. for each of the major ethnicities with sufficient data for comparison. Each subpanel shows the percentages of total horizontal strabismus for different ethnicities due to ET (blue) and XT (red), obtained from population-based studies. The graph furthermore compares the percentages obtained through population-based studies (darker color) with those from clinic-based studies (light blue and pink colors). The error bars are 95% confidence intervals. Overall, the clinic-based studies underestimate by about 14% the frequency of XT, suggesting reduced XT presentation in the clinic compared to ET. Abbreviations: N, North; E, East, S, South.

Fig. 8A-B. Number of studies over time and their impact by ethnicity. A. The number of population-based studies per decade is indicated between 1860 and 2025, for the largest six ethnicities (Caucasian, East Asian, South Asian, African, Middle East and Latino/Hispanics). Note that only two ethnicities (Caucasians and East Asians) have sufficiently large numbers of studies per decade to allow longitudinal analyses over several generations (see Fig. 10A,B). B. Citations of studies surveying different ethnicities were compiled on October 4-5, 2025 based on the Web of Science, Core collection.[F] The pie chart shows that the Caucasian impact is overrepresented by three-fold compared with the actual contribution to the world population, which explains, in part, why the prevalence of horizontal strabismus, and especially the prevalence of esotropia (ET), was significantly overestimated. Only 1/3 of the world population has more ET than exotropia (XT), but based on citations of studies, about 2/3 of the impact was from studies that examined populations with ET exceeding XT.

Fig. 9A-B. Funnel plots for population-based studies on esotropia (ET) in Caucasians (A) and for exotropia (XT) in East Asians (B). The funnel for ET in Caucasians is symmetric, with very few outliers, suggesting no publication bias. The funnel for XT in East Asians shows the presence of a distinct subgroup: the most recent data (after 2010) from China and Nepal form an apparent subgroup, indicated by orange dots (2011-2025), when compared with studies from other East Asian countries.

Fig. 10A-B. Bar graphs showing secular (generational) differences in esotropia (ET) and exotropia (XT) prevalence among Caucasians in Europe (A) and among East Asians (B). A. Caucasians in Europe had a consistent prevalence of ET between 1.5% and 2% from the 1860s until about 1930, but underwent an ET epidemic from approximately 1960 until 1990, with a doubling of the ET prevalence (blue), and with a subsequent decline to the original base level in the most recent generation (1990-2025); XT prevalence (red), on the other hand, gradually increased from 1860 to 2025. One outlier for XT was removed for the sparse data set of 1876 to 1905 (Tukey's Hinges with k=1.5). B. All East Asian studies other than those in China and Nepal show a gradual increase in XT prevalence (red) over the last few decades, with a modest decrease in ET prevalence (blue) after 1995. Studies from China and Nepal (hatched bars) in 2011-2025 show a statistically highly significant increase of XT, that is not seen in the other East Asian populations. Error bars are standard errors of the mean (SEM).

TABLES

TABLE 1. Ranges of strabismus prevalences quoted in reviews.

Author	Year	Range
Keiner	1951	2% - 3%
Waardenburg	1954	2% - 4%
Frandsen	1960	0.5% - 3%
Gansner	1968	3% - 5%
Rantanen & Tommila	1971	0.9% - 4.5%
De Decker & Tessmer	1973	2.5% - 7.4%
Aichmair et al.	1992	4% - 6%
Stidwill	1997	4.2% - 6%
Kvarnström et al.	2001	3.1% - 6.7%
Ziakas et al.	2002	2.5% - 4%
Donnelly et al.	2005	2.5% - 4.6%
Matsuo & Matsuo	2005	1.2% - 8.7%
Grönlund et al.	2006	0.3% - 3.9%
Robaei et al.(a)	2006	0.5% - 9.9%
Multi-ethnic	2008	0.3% - 4.4%

SUPPLEMENTAL MATERIALS

Supplemental Table 1. Esotropia/exotropia (ET/XT) ratio in different regions. Population-based, 315 studies with 340 cohorts.

* 0.5 was added to each value for the ET/XT ratio when the value was 0, to avoid a zero in the denominator or enumerator, according to Sweeting et al., 2004.[758] Cohort type: C, community; S, School or Pre-school; B, Birth cohort. Yrs, years; Hor. Strab, horizontal strabismus; ET, esotropia, XT, exotropia. Duplicate publication of the same cohort is indicated in *italics*. Studies reporting exclusively on ages 2 years or younger are gray-shaded.

Footnotes

Duelund, 2024 and 2025 report only new cases, not those already treated.

The papers by Lin et al., 2013, 2014 and 2016 apparently used the same cohort, yet the prevalence of exotropia was reported as 2.71%, 6.59%, and 1.69%, respectively. The latest version is assumed to be the correct value and is used in our meta-analysis.

Supplemental Table 2. Esotropia/exotropia (ET/XT) ratio in different regions. Clinic-based, 374 studies with 374 cohorts.

* 0.5 was added to each value for the ET/XT ratio when the value was 0, to avoid a zero in the denominator or enumerator, according to Sweeting et al., 2004.[758] Abbreviations: yrs, years; ET, esotropia, XT, exotropia. Duplicate publication of the same cohort is indicated in *italics*.

First Author	Year	Ethnicity/Region	Patients (number)	Age yrs	ET %	XT %	ET/XT Ratio

Supplemental Table S3. Analysis of Heterogeneity.

Esotropia

Population	n	I^2	I^2 95% CI	τ^2	τ^2 95% CI
Overall	292	96.7%	[96.4%; 96.9%]	0.9984	[0.8631; 1.2992]
Caucasian	89	97.7%		0.3492	
Native American	10	60.0%		0.3661	
African American	9	86.2%		0.1491	
Latino/Hispanic	13	90.4%		0.2699	
Eskimo/Inuit	2	72.7%		0.2167	
Africa East, North	17	88.6%		0.9394	
Africa West	18	59.7%		0.4045	
Middle East	18	91.5%		0.5861	
Persian	18	53.7%		0.0784	
South Asia NW	9	84.4%		0.3002	
South Asia SE	16	89.6%		0.8190	
East Asia	62	86.9%		0.3105	
Oceania	11	71.2%		1.0001	

CI, confidence interval; NW, Northwest; SE, Southeast. The total number of studies exceeds the number given in Fig. 2, because some studies report on cohorts of different ethnicities,[147,170,255,510,545,D] while others do not distinguish multiple ethnicities[657,I] and therefore are not included in this analysis.

Exotropia
