Abstract

Background

Approximately 1.2 million Rohingya refugees currently reside among the 33 refugee camps located in Cox's Bazar near the Bangladesh-Myanmar border where educational needs remain a critical humanitarian concern. This study aimed to estimate the prevalence of educational needs among Rohingya refugee children, elucidate predominant reasons for these needs, and identify characteristics associated with educational needs to inform targeted humanitarian relief efforts.

Methods

This study utilized participant data collected during the 2023 Joint Multi-Sectoral Needs Assessment - a representative cross-sectional household survey. Education age children within the sampled households were assigned a severity score categorized as either stressed, severe or extreme based on responses to questionnaire items that capture educational access, learning conditions, and protection factors. Multinomial logistic regression was used to examine factors associated with children in severe and extreme educational need.

Results

Among 8,408 education age children surveyed from 2,959 households, 29.6% of children were found to be in severe educational need and 10.1% of children were in extreme educational need. After adjustment for individual characteristics and household vulnerability factors, severe educational needs were associated with head of household age 45-59 (aRRR= 1.24 [95%CI: 1.00–1.53]), head of household age 60+ (aRRR= 1.39 [95%CI: 1.09–1.76]), female headed households (aRRR= 1.30 [95%CI: 1.09–1.54]), early education age boys (aRRR= 4.33 [95%CI: 3.44–5.46]), early education age girls (aRRR= 5.01 [95%CI: 3.88–6.46]), teenage boys (aRRR= 3.81 [95%CI: 3.18–4.57]), and teenage girls (aRRR= 16.07 [95%CI: 12.79–20.20]; p<0.001) relative to their primary school age counterparts, primary school age girls (aRRR= 0.75 [95%CI: 0.61–0.93]) relative to primary school

age boys, and teenage girls (aRRR= 3.18 [95%CI: 2.65–3.83]) relative to teenage boys. Post

adjustment, factors associated with extreme educational needs included head of household age 18-24

(aRRR= 1.73 [95%CI: 1.09–2.74]), age 45-59 (aRRR= 1.57 [95%CI: 1.13–2.18]) and age 60+

(aRRR= 1.55 [95%CI: 1.07–2.25]), female headed households (aRRR= 1.58 [95%CI: 1.24–2.00]),

early education age boys (aRRR= 3.44 [95%CI: 2.12–5.60]), early education age girls (aRRR= 2.44

[95%CI: 1.50–3.97]), teenage boys (aRRR= 6.82 [95%CI: 4.79–9.69]), teenage girls (aRRR= 34.60

[95%CI: 25.12–47.65]; p<0.001) relative to their primary school age counterparts, and teenage girls

(aRRR= 5.86 [95%CI: 4.63–7.43]) relative to teenage boys.

Conclusion
41

42 Educational needs remain highly prevalent among Rohingya refugee children driven by structural

43 deficiencies and further aggravated by household vulnerabilities. Over 20 projects led by local

44 humanitarian authorities are currently providing targeted relief to those in educational need but are

45 threatened by funding cuts that continue to jeopardize the educational rights of Rohingya refugees.

46 **Keywords:** Rohingya; Humanitarian Emergency; Refugee; Refugee Camps; Human Rights;

Introduction
47

Eight years on from the mass displacement events in late 2017, approximately 1.2 million Rohingya

refugees are currently sheltering within 33 congested camps of Cox's Bazar near the Bangladesh-

Myanmar border. Meeting the humanitarian needs of Rohingya refugees remains imperative for the

international community but has met a critical juncture. While the human rights violations have

worsened displacing an additional 150,000 people, the international attention to the protracted crisis

has waned, and the global commitment to unequivocally affirm the rights of Rohingya refugees has

withered [1-3]. The multifaceted challenges that confront Rohingya refugees are characterised by

deteriorating humanitarian conditions, entrenched population vulnerabilities, aid dependencies,

concurrent domestic needs to support host communities in Bangladesh and resurgent persecution in

Myanmar that has dashed hopes of repatriation [1-5]. The timing of these intersecting factors occurs

amid a backdrop of changing geopolitical landscapes and receding humanitarian budgets that has

jeopardized the delivery of essential humanitarian relief services [4-8].

This study builds upon prior analysis investigating the sector-specific drivers and household

determinants of humanitarian needs among Rohingya refugees surveyed during the 2023 Joint Multi-

Sectoral Needs Assessment (J-MSNA). The 2023 J-MSNA marks the fifth annual needs analysis

conducted by the Inter-Sector Coordination Group (ISCG) to strategically inform the humanitarian

response plan. Prior findings highlighted the education sector as the predominant driver of extreme

humanitarian needs. Preliminary analysis foreshadowed gendered effects that disproportionately

impact young girls and raised serious child protection concerns that require more sensitive in-depth

sector-specific analysis. As such, this study aimed to estimate the prevalence of Rohingya refugee

children experiencing educational needs, elucidate predominant reasons among children in need to

inform sector-specific interventions and identify characteristics associated with educational needs to

strengthen targeted relief efforts by local humanitarian authorities.

Methods

Study design, population and sampling strategy

This study draws upon anonymized participant data from the 2023 J-MSNA, a representative cross-

sectional survey of Rohingya households within the 33 refugee camps of Cox's Bazar [9]. The

primary data collection was conducted by the REACH Initiative in conjunction with sector-specific

authorities and local enumerators. The dataset was accessed on the 27th of March 2025 under license

approved by UNHCR. The study population included all Rohingya refugee households registered

within the 33 camps of Cox's Bazar [10,11]. An exhaustive sampling frame of household addresses

was compiled by camp authorities [10,11]. A total of 3,465 households were selected for data

collection using a stratified (camp specific) simple random sampling technique [10,11]. The number

of households selected for sampling at each camp were guided by a single proportion sample size

calculation that derived the minimum number of households needed to ensure camp-specific results

could be concluded with a minimum level of precision (10% margin of error) at a 95% confidence

level [10,11]. The sample size was adjusted for the finite household population that were eligible for

selection at each camp and inflated by an additional 10% to mitigate non-response [10,11]. Of the

3,465 households selected for sampling, a total sample size of 3,400 households (response rate

exceeding 98%) were surveyed between August 27th and September 17th 2023 with complete data

(without missing fields) pertaining to 18,172 household members.

Data collection

Data were collected through in-person household interviews administered by trained enumerators

using a validated structured questionnaire that captured standardized humanitarian indicators and

sector-specific items [10,11]. Gender-balanced field teams (comprising male and female interviewers)

conducted interviews with an adult (age 18 or older) respondent of the same gender (self-identified)

[10,11]. Responses were digitally recorded using the KoBo Collect application on mobile devices and

routinely uploaded to a secure UNHCR server [10,11]. Raw participant data was cleaned according to

the REACH Initiative's minimum standards protocol with a final de-identified dataset provided for

statistical analysis [10,11]. Verbal informed consent was secured from all household respondents and

formally recorded in the deidentified dataset. Respondents were informed of the survey's objectives,

the voluntary nature of their participation, measures to protect response confidentiality and

prerogative to decline any question or discontinue the interview at any time. Enumerators were
educated on the principles of participant safeguarding and trained to provide formal referral protocols
upon discovery of urgent protection or health concerns.

Variables

The primary outcome was education severity score assigned to each education age child (age 3-18)
based on responses to questionnaire items that capture the four dimensions of educational access,
learning conditions, protection and aggravating circumstances. Education severity scores were
assigned based on recommended criteria outlined in the global education cluster severity classification
manual, Joint Intersectoral Analysis Framework (JIAF) and Multi-Sectoral Needs Index [10,12,13].
Severity was scored according to the JIAF five-point intersectoral severity classification scale ranging
from minimal (score=1) to catastrophic (score=5). The five-point scale was adapted to a three-point
scale in line with the J-MSNA due to the absence of formal education services required to assign the
minimal severity score and participant/household level data rather than response level data required to
infer catastrophic sectoral collapse (score=5). The adapted three-point scale categorised each child's
education severity score as either stressed (score=2), severe (score=3) or extreme (score=4). Stressed
(score=2) was defined as accessing non-formal education in a protected environment offering
acceptable learning conditions. Severe (score=3) was classified as either not accessing education due
to non-aggravating circumstances, or accessing non-formal education in a protected environment but
experiencing poor learning conditions or minor safety issues that do not present an immediate threat
to the child's wellbeing. Extreme (score=4) was defined as either not accessing education services due
to aggravating circumstances, or attending an unprotected learning environment due to serious safety
issues that endangers the child's well-being. Aggravating circumstances correspond to the most severe
accessibility barriers such as marriage or pregnancy, child paid and unpaid labour to support the
household instead of attending school, recruitment by armed groups, discrimination and safety threats
whilst travelling to or at school [10,13]. Unprotected learning environment included armed group
recruitment, school attacks, gender based or sexual violence, and discrimination based on the child's
ethnic, gender or religious identity [12,13]. The underlying reason for each child's education severity
score were utilised as secondary outcomes to evaluate predominate drivers of educational needs.
Individual characteristics of education age children and household vulnerability factors evaluated for
association with educational needs were identified from previous J-MSNA research, Refugee Influx
Emergency Vulnerability Assessments (REVA), and funding impact analysis conducted by the World
Food Programme [6,7,14,15]. Age groups were assigned according to previous camp levels findings
and appropriate cutoff points identified from trends observed over increasing age [16]. Subgroups
among education age children (age 3-18) included early education age children (age 3-4), primary
school age children (age 5-11) and teenage children (age 12-18). Head of household age was

categorized into 10-year age groups. Marital status was collapsed into a binary variable that included

married and single participants (no partner/separated/divorced/widowed) due to limited observations.

Head of household disability status was classified as a binary variable corresponding to participants

citing either "a lot of difficulty" or "cannot do it at all" to any of the six functional domains as per the

Washington Group Short Set (WG-SS) guidelines [18]. Monthly household income per capita

(household members) was categorized according to quartiles and utilized to investigate associations

with financial vulnerability.

Statistical analysis

All results were computed using Stata version 19.5 survey functions that accounted for the stratified

sampling design, adjusted for the clustering of education age children within the same household and

controlled for differential probability of household selection between the camps (strata) using survey

weights computed as the inverse probability of selection [17].

Descriptive statistics were used to analyse demographic characteristics of sampled households and

education age children. Weighted frequencies and percentages were reported for categorical variables.

Median and interquartile range (IQR) or mean and standard deviation (SD) were reported for

continuous variables depending on symmetry. Prevalence estimates regarding the proportion of

children and households experiencing educational needs were reported as weighted percentages with

95% confidence intervals (95% CIs) for precision.

Education severity scores and their attributable reasons were disaggregated by age and gender. The

distribution of severity scores and reported reasons were assessed over increasing age and by gender

to assess linear trends. Multinomial bivariate and multivariate logistic regression analysis was

conducted to investigate individual characteristics and household factors associated with severe and

extreme educational need. Unadjusted relative risk ratios (RRR) and adjusted relative risk ratios

(aRRR) were reported for bivariate and multivariate estimates respectively. A threshold value of $p \leq$

0.05 was used to conclude statistical significance and 95% CIs were reported for precision using

design-adjusted standard errors computed via Taylor series linearization.

Potential effect modification was considered between head of household gender and marital status to

investigate concentrated effects among single female headed households. Two-way age and gender

interactions among education age children (age-gender and gender-age) were investigated using both

stratified analysis and interaction terms. Gender-age interactions were investigated using stratified (by

gender) analysis reporting the relative risk associated with age groups among boys and among girls.

Age-gender interactions were investigated using interaction terms to evaluate the relative risk

associated with girls relative to boys within the same age group. Pairwise correlation and variance

inflation factor (VIF) analysis were conducted to evaluate potential problematic multicollinearity.

Results

Participant characteristics

Among the 3,400 total households sampled, 441 households did not contain education age children (age 3-18) and were excluded from subsequent analysis (Table 1). A total of 8,408 education age children were surveyed from the remaining 2,959 households across the 33 camps. The number of households without education age children (n=441) did not significantly differ between the camps (p >0.05). The proportional contribution of each camp to the overall sample showed minimal variation (mean change= +0.5%; range: -12.6% to +8.7%) before (N=3,400) and after (N=2,959) the exclusion of households without education age children. The number of households and education age children sampled per camp was approximately normally distributed with a mean of 90 households (SD= 35; Table 1) and 255 education age children (SD= 95; Table 1) respectively. The median head of household age was 39 years (IQR: 30 – 50; Table 1) and the majority of households were male headed (79.8%; Table 1). Approximately half of surveyed children were aged between 5-11 years (47.4%; Table 1) and the proportion of boys sampled (50.3%; Table 1) was slightly higher than the proportion of girls (49.7%; Table 1). Less than two-thirds of education age children were enrolled and regularly attending informal education within the camps (60.3%; Table 1). The prevalence of children in educational need was 39.7% (95% CI: 38.4% – 41.0%) and almost two-thirds of households contained at least one child in educational need (65.7% [95% CI: 63.8% – 67.5%]).

Table 1. Characteristics of sampled households (N= 2,959) and education age children (N= 8,408)

	Summary*
Households per Camp, Mean (N= 2,959)	90 (SD: 35)
Education Age Children per Camp, Mean (N= 8,408)	255 (SD: 95)

Extreme (Severity Score=4) [c]	850 (10.1%)
Prevalence of Educational Need	
Children in Educational Need (N= 8,408) [d]	39.7% [95% CI: 38.4% – 41.0%]
Households in Educational Need (N= 2,959) [e]	65.7% [95% CI: 63.8% – 67.5%]

* Estimates are relative to either the total number of sampled households with education age children (N= 2,959) or the total number of education age
children surveyed within the households (N= 8,408). Summary statistics are weighted frequency and weighted percentages for categorical variables,
weighted median (IQR) for asymmetrically distributed continuous variables, weighted mean (SD) for symmetrical continuous variables, or
weighted population prevalence (%) and 95% CIs for outcome variables.
[a] Stressed was defined as accessing non-formal education in a protected environment offering acceptable learning conditions [10,12,13].
[b] Severe was defined as either not accessing education due to non-aggravating circumstances, or accessing non-formal education in a protected
environment but under poor learning conditions or minor safety issues that do not present an immediate threat to the child's wellbeing [10,12,13].
[c] Extreme was defined as either not accessing education due to aggravating circumstances, or attending an unprotected learning environment due to
serious safety issues that endangers the child's well-being [10,12,13].
[d] Children in educational need was classified as severe or extreme education severity scores (severity score= 3+) as per MSNI [10]. Children in
education need defined as per JIAF and education cluster guidelines - Education age children in the areas affected by crisis who do not have access
to protective education and acceptable learning conditions, which can negatively impact (i) their physical and psychosocial wellbeing, (ii) cognitive
development, and (iii) their ability to meet their future needs [12,13].
[e] Households in educational need categorised as households with at least one child in educational need as per MSNI [10].

Educational Needs by Age and Gender

Approximately half (54.3%; Figure 1A) of early education age children (3-4 years) were enrolled and regularly attending informal education with similar results observed among boys (52.4%) and girls (56.1%). An additional 40.4% were found to be in severe educational need mostly attributable to "unable to register or enrol" (26.5%; Figure 1B), "too young" (5.3%; Figure 1B) and "education is not a priority" (3.3%; Figure 1B). A further 5.3% of early education age children were experiencing extreme educational need predominantly due to "protection risks while commuting to school" (4.3%; Figure 1B).

Most primary school age children (5-11) were enrolled and regularly attending informal education (83.3%; Figure 1A) with similar results observed between boys (81.8%; Figure 1A) and girls (84.9%; Figure 1A). An estimated 13.9% of primary school age children (5-11) were in severe educational need predominantly attributable to "attending madrasa instead" (4.9%; Figure 1B), especially among boys (7.4%; Figure 1B) compared to girls (2.3%; Figure 1B). A relatively small proportion of primary school age children (5-11) were found to be in extreme educational need (2.8%; Figure 1A). Only a third (34.4%; Figure 1A) of teenage children age 12-18 were enrolled and regularly attending informal education with significant heterogeneity observed between boys (49.1%; Figure 1A) and girls (20.1%; Figure 1A). Most teenage children were experiencing severe educational needs (44.9%; Figure 1A) with greater prevalence observed among teenage girls (50.6%; Figure 1A) compared to boys (38.9%; Figure 1A).

Figure 1A. Education severity scores among education age children by age group and gender.

[a] Stressed was defined as accessing non-formal education in a protected environment offering acceptable learning conditions [10,12,13].
[b] Severe was defined as either not accessing education due to non-aggravating circumstances, or accessing non-formal education in a protected
environment but under poor learning conditions or minor safety issues that do not present an immediate threat to the child's wellbeing [10,12,13].
[c] Extreme was defined as either not accessing education due to aggravating circumstances, or attending an unprotected learning environment due to
serious safety issues that endangers the child's well-being [10,12,13].

Figure 1B. Attributable reason for education severity scores among education age children by age group and gender.

229
[a] Stressed was defined as accessing non-formal education in a protected environment offering acceptable learning conditions [10,12,13].
[b] Severe was defined as either not accessing education due to non-aggravating circumstances, or accessing non-formal education in a protected
environment but under poor learning conditions or minor safety issues that do not present an immediate threat to the child's wellbeing [10,12,13].
[c] Extreme was defined as either not accessing education due to aggravating circumstances, or attending an unprotected learning environment due to
serious safety issues that endangers the child's well-being [10,12,13].
[d] Rarely reported severe reasons (<1%) observed among all cohorts were recoded as "other" rather than individually categorised for visual clarity.
"Other" includes the following reasons and percentages:
Children Age 3-4: Lack of Schools (0.3%), Language Issues (1.3%), Decline/Do not Know (0.6%)
Boys Age 3-4: Lack of Schools (0.2%), Language Issues (1.5%), Decline/Do not Know (0.7%)
Girls Age 3-4: Lack of Schools (0.4%), Language Issues (1.2%), Decline/Do not Know (0.4%)
Children Age 5-11: Illness (0.1%), Lack of Schools (0.2%), Decline/Do not Know (0.5%)
Boys Age 5-11: Cannot Afford Education Costs (0.1%), Illness (0.1%), Lack of Schools (0.1%), Decline/Do not know (0.5%)
Girls Age 5-11: Illness (0.1%), Lack of Schools (0.4%), Decline/Do not Know (0.4%)
Children Age 12-18: Cannot Afford Education Costs (0.2%), Child Uninterested (0.3%), Home Based Learning (0.4%), Inadequate Curriculum
(0.2%), Decline/Do not Know (2.4%)
Boys Age 12-18: Cannot Afford Education Costs (0.3%), Child Uninterested (0.5%), Home Based Learning (0.7%), Inadequate Curriculum (0.1%),
Decline/Do not Know (1.8%)
Girls Age 12-18: Cannot Afford Education Costs (0.1%), Child Uninterested (0.1%), Home Based Learning (0.1%), Illness (0.1%), Inadequate
Curriculum (0.2%), Decline/Do not Know (3.0%)

The analysis of education severity scores over age and by gender illustrated that boys and girls were

largely coupled between ages 3-11 (Figure 2A). An inverse proportional relationship was also evident

between stressed and severe education severity scores with a steady proportion of children age 3-11

experiencing extreme educational needs. A sharp decline in the proportion of children enrolled and

regularly attending school was observed over age 12-18. Gendered disparities regarding severe and

extreme educational needs emerged between ages 11-12 (Figure 2A). A rapid proliferation of severe

educational needs was observed among adolescent girls age 12-15 (Figure 2A), predominantly

attributable to "education is not a priority" (Figure 2B) and "inadequate male-female separation"

(Figure 2B). A linear trend between extreme educational needs and increasing age was evident among

girls age 11-18 (Figure 2A). The increasing trend in the proportion of girls age 11-15 experiencing

extreme educational need was mostly attributable to "child helping at home instead" (Figure 2B), or

not attending due to "protection risks while commuting to school" (Figure 2B). In contrast, the

continuous rise in extreme educational needs among girls age 16-18 was primarily due to "marriage or

pregnancy" (Figure 2B). Educational needs among boys remained relatively constant between age 12-

15 then increased between 16-18 predominantly attributable to "education is not a priority" (Figure

2B) and "child helping at home instead" (Figure 2B).

Figure 2A. Education severity scores over increasing age (3-18) and by gender (children, boys, girls).

Figure 2B. Reported reason for educational needs over increasing age (3-18) and by gender (children, boys, girls).

269 **Household characteristics associated with Educational Needs**

In unadjusted analysis, severe and extreme educational needs were associated with all head of

household age groups relative to those age 25-34, female headed households, early education age

boys and teenage boys relative to primary school age boys, early education age girls and teenage girls

relative to primary school age girls, early education age girls relative to early education age boys, and

teenage girls relative to teenage boys.

After adjustment in multivariable analysis, severe educational needs were associated with head of

household age 45-59 (aRRR= 1.24 [95%CI: 1.00–1.53]), head of household age 60+ (aRRR= 1.39

[95%CI: 1.09–1.76]), female headed households (aRRR= 1.30 [95%CI: 1.09–1.54]), early education

age boys (aRRR= 4.33 [95%CI: 3.44–5.46]) and teenage boys (aRRR= 3.81 [95%CI: 3.18–4.57])

relative to primary school age boys, early education age girls (aRRR= 5.01 [95%CI: 3.88–6.46]) and

teenage girls (aRRR= 16.07 [95%CI: 12.79–20.20]; p<0.001) relative to primary school age girls,

primary school age girls (aRRR= 0.75 [95%CI: 0.61–0.93]) relative to primary school age boys, and

teenage girls (aRRR= 3.18 [95%CI: 2.65–3.83]) relative to teenage boys.

Post adjustment, extreme educational needs were associated with head of household age 18-24

(aRRR= 1.73 [95%CI: 1.09–2.74]), age 45-59 (aRRR= 1.57 [95%CI: 1.13–2.18]) and age 60+

(aRRR= 1.55 [95%CI: 1.07–2.25]), female headed households (aRRR= 1.58 [95%CI: 1.24–2.00]),

early education age boys (aRRR= 3.44 [95%CI: 2.12–5.60]) and teenage boys (aRRR= 6.82 [95%CI:

4.79–9.69]) relative to primary school age boys, early education age girls (aRRR= 2.44 [95%CI:

1.50–3.97]) and teenage girls (aRRR= 34.60 [95%CI: 25.12–47.65]; p<0.001) relative to primary

school age girls, and teenage girls (aRRR= 5.86 [95%CI: 4.63–7.43]) relative to teenage boys.

The multivariate model indicated adequate fit over a null model (p<0.001) and no evidence of

problematic multicollinearity was observed. All pairwise correlations between independent variables

were below 0.7 and the mean VIF was 1.5 with no extreme outliers (VIFmax <10). No statistically

significant effect modification was present between female headed households and marital status with

main effects reported in consequence.

Table 2. Individual factors and household characteristics associated with severe and extreme educational needs

* Statistically significant at p ≤ 0.05 and emboldened.
[a] Estimates from a duplicate model with interaction terms applied to investigate effect modification among single/divorced/widowed female headed households relative
to married female headed households. Note that estimates reported for female headed households represent the main effects among all female headed households
rather than the subgroup of married female headed households. These additional estimates have been reported to evidence the absence of statistically significant effect
modification between female headed households and marital status. All multivariable estimates were adjusted for main effects only.
[b] Disability classified as per Washington Group Short Set (WG-SS) guidelines: Respondent cited "a lot of difficulty" or "cannot do it at all" to any of the six functional
domains (seeing, hearing, walking or climbing stairs, remembering or concentrating, self-care, and communication) [18].
[c] Monthly household income per capita.

Discussion

The demographic characteristics of households with education age children closely mirror the
characteristics of all sampled households previously analysed [19]. Prior findings demonstrated the
strong concordance between all households sampled during the 2023 J-MSNA and the population
characteristics from UNHCR's database of registered Rohingya refugees [19]. The insignificant
difference between the number of households without education age children excluded across the 33
refugee camps (n=441), retention of the demographic profile observed among all sampled households,
and the demographic profile's close alignment with the population characteristics of all Rohingya
refugees registered in UNHCR's database strongly support the representativeness of sampled
participants and hence generalisability of our results [19].

Notwithstanding extensive humanitarian relief efforts delivered by local authorities, the findings
highlight that almost two-thirds of households (65.7% [95% CI: 63.8% – 67.5%]; Table 1) and 2-in-
every-5 children age 3-18 were in educational need (39.7% [95% CI: 38.4% – 41.0%]; Table 1).
Disaggregation by age group illustrated the higher prevalence of educational needs among early
education age children (age 3-4) and teenage children (age 12-18). Further disaggregation by gender
evidenced the similarities among boys and girls between ages 3-11, followed by the rapid divergence
of educational needs between ages 12-18. These coupled-decoupled age-gender dynamics are best
illustrated by the distribution of educational needs and their attributable reasons over increasing age.
Additionally, the age-gender and gender-age dynamics are further reinforced by the logistic regression
results that demonstrated that educational needs were significantly associated with age groups among
girls, age groups among boys, and girls relative to boys within the same age group. The predominant
reasons for educational needs by gender and over increasing age vividly illustrate the gendered
dimension that emerges among teenage children to drive the widening disparity observed between
teenage boys and teenage girls over increasing age.

The associations observed between educational needs and the age-gender characteristics of education
age children persisted with limited attenuation after adjustment for common household vulnerability
factors. These findings suggest the predominant role of structural factors and systemic issues within
the education sector rather than primarily influenced by household vulnerability factors. These
quantitative results align with previous sector-specific analysis that highlight the limited learning
opportunities for teenage girls and lack of reintegration support for out-of-school teenagers
transitioning from at-home to face-to-face learning as COVID-19 restrictions subsided [5,14,20,21].
In contrast, the elevated risk associated with female headed households, young adult (18-24) headed
households and elderly (age 45+) headed households draw focus towards the survival pressures that
provoke households to deprioritise their children's education. These pressures are reinforced by the
underlying reasons attributed to education severity scores and their gendered impacts that are highly
concentrated among teenage girls. The trends regarding deprioritization and educational needs

highlight the intersections between the education sector and the broader survival pressures within the
camps that provoke households to adopt negative livelihood coping strategies. In addition, the rising
prevalence of childhood marriage and early pregnancy reveals the inextricable links between
deteriorating educational needs and serious child protection issues that demand prompt remediation
efforts.

Limitations

The findings should be interpreted within the context of multiple strengths and limitations. Selection
bias was minimised through stratified simple random sampling of households within each camp.
Sampling bias was mitigated through the use of survey weights that adjusted for the disproportionate
probability of households selected for sampling between the 33 camps. The face-to-face interviews
conducted by gender-balanced enumerator teams prevented the sampling bias observed during
previous J-MSNA iterations conducted during COVID-19 restrictions that collected data through
phone interviews and led to an overrepresentation of male respondents with higher rates of phone
ownership. However, the findings are predominantly limited by the use of self-reported data collected
from proxy respondents on behalf of the household that may consequentially introduce measurement
bias and undermine the accuracy of the results.

Implications for Practice

More than 20 projects are currently providing relief to Rohingya refugee children in educational need
led by humanitarian agencies, international authorities and non-government organisations [5]. These
projects include school feeding programs for disadvantaged students, reuptake programs for out-of-
school children, accelerated learning programs for students who are at risk of falling further behind
and restructuring of learning centres to provide female-only classrooms that redress sociocultural
barriers among teenage girls [2,8]. The continuity of these projects are critical to affirm the right to
education among Rohingya refugee children yet remain desperately underfunded at just 15% of their
stated requirements [22]. The detrimental impacts of funding cuts among the shock-prone education
sector are vividly evident having forced the closure of 43% of learning facilities that denied access to
education for approximately 200,000 Rohingya children [23,24]. Rapid restructuring efforts in
conjunction with community adaptation have secured the gradual recovery of the education sector.
However, these gains remain fragile and unable to deliver the sustained relief that the protracted crisis
and their multidimensional complexities demand.

Conclusion

Educational needs remain highly prevalent among Rohingya refugee children in Cox's Bazar. Approximately a third of children age 3-18 were found to be in severe educational need and one in ten were experiencing extreme educational need. The findings reveal pronounced age-gender dynamics with teenage girls experiencing dramatically elevated educational needs driven by intersecting structural challenges, survival pressures, sociocultural barriers and child safety threats that continue to jeopardize the wellbeing of vulnerable children. Addressing the educational needs of Rohingya refugee children remains imperative to heal the gendered harms and generational impacts of the protracted crisis. Ameliorating the scale of children in educational need, their complexities and intersectoral dependencies requires not only intensive but sustained humanitarian efforts that remain undeliverable within the confines of receding financial support from the international community that continues to jeopardize the rights of the world's largest stateless population.
