In late December 2019, Chinese authorities reported a cluster of pneumonia cases of unknown aetiology in Wuhan, China¹. A novel strain of coronavirus named Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) was isolated and identified on 2 January 2020². Human-to-human transmission have been confirmed by a study of a family cluster and have occurred in health-care workers^{3,4}. Until 10 February 2020, 42638 cases of 2019 novel coronavirus disease (COVID-19) have been confirmed in China, of which 31728 came from Hubei Province (Figure). Wenzhou, as a southeast coastal city with the most cases outside Hubei Province, its policy control and epidemic projections have certain references for national and worldwide epidemic prevention and control. We described the epidemiologic characteristics of COVID-19 in Wenzhou and made a transmission model to predict the expected number of cases in the coming days.

Methods

In this epidemiologic and modelling study, we first gathered transmission data for 434 confirmed COVID-19 patients in the ongoing Wenzhou outbreak from the the National Health Commission of the People's Republic of China and the Health Commission of Wenzhou by February 10, 2020. We then investigate a deterministic (susceptible-exposed-infectious-recovered) SEIR compartmental model based on the clinical progression of the disease, epidemiological status of the individuals, and the intervention measures to inferred the basic reproductive number of SARS-CoV-2 and the transmission among Wenzhou and three prefecture-level cities. Finally, we forecasted and compared the spread of SARS-CoV-2 across Wenzhou (Southeastern), Shenzhen (Southern), Zhengzhou (Central) and Harbin (Northern), accounting for the effect of the Wenzhou quarantine implemented since Jan 27, 2020 and other interventions. see https://github.com/ZhangBuDiu/WZ_COVID-19 for R code, case data, and prepared datafiles.

Results

A total of 434 incidence, 31 severe case, 99 hospital discharges and 5304 probable COVID-19 cases were reported before February 10, 2020, and 168 patients who visited Wuhan after the onset of the SARS-CoV-2 epidemic. The median age of persons with COVID-19 was 47 years; 48 cases (11.1%) occurred in persons 65 years of age or older, and 5 (1.2%) were in children younger than 15 years of age (Table). The maximum number of illness onset in Wenzhou appeared on January 26 (38 cases). Since January 27, the incidence per day in Wenzhou has continued to decline is likely to be due to isolation of people return to Wenzhou, implementation of region quarantine and suspension of public transportation system. Under the current control efforts, we estimate that the daily incidence by March 3-9, 2020 will drop to 0 in Wenzhou using SEIR model. The total number of affected people is 538 (95% CI: 534-542). Estimated of the basic reproduction numbers, R_0 , were 2.91 (95% CI: 2.35-3.57) for Wenzhou, 2.53 (95% CI, 1.86 to 3.34) for Shenzhen, 5.95 (95% CI, 5.36 to 6.67) for Zhengzhou, and 3.35 (95% CI, 3.07 to 3.68) for Harbin. Figure shows the trajectories of the epidemic for Wenzhou, Shenzhen, Zhengzhou and Harbin. We classified these cities to Input-Burst, Input-Control, Control-Relaxation and Control-Missing based on epidemic dynamics and control measures. We found that the epidemic in Wenzhou was composed of outsiders (people with a visit history to Hubei) and local people, while the epidemic in Shenzhen was mainly composed of outsiders. Under strict implemented control measures, epidemic gradually subsided in both Wenzhou and Shenzhen.

Discussion

Although the current epidemic of SARS-CoV-2 in China is unprecedented in scale, clinical presentations greatly resemble SARS-CoV. The higher number of infections may be due to the late identification of pathogens, the host's ability to hide infection symptoms and high transport capacity of China. As we known, estimate of epidemic dynamics and predictions are of crucial importance for public health planning and control measurement ^{5,6}. In this study, we provide an assessment of the transmission dynamics and predictions of the future spread of COVID-19

among four cities. Forward projections suggest that the Wenzhou and Shenzhen epidemic will end before Zhengzhou and Harbin, which result from substantial and draconian measures that limit population movements and drastically reduce within-population contact rates, such as greater community engagement, cancellation group gatherings, school closures, and work-from-home arrangements.

Author Contributors: J. Qu, J. Su and L. Xu conceived and designed the study; J. Yuan, L. Xu G. Zhang, R. Zhang and Y. Huang collected and analysed data; J. Yuan, J. Su, L. Xu and J Qu drafted the manuscript.

Conflicts of interest: We declare no competing interests.

Funding: This work was supported by the Key Program of National Natural Science Foundation of China (81830027) to J. Qu; the National Natural Science Foundation of China (61871294) to J. Su; the Key Research and Development Program of Zhejiang Province (2020C03036) to L. Xu

Role of the Funders/Sponsors: The study funders/sponsors had no role in the design and conduct of the study; collection, management, analysis, and interpretation of the data; preparation, review, or approval of the manuscript; and decision to submit the manuscript for publication.

Table. Epidemiologic Characteristics and Variables of Patients with COVID-19 in Wenzhou as of February 10, 2019.

Variable	Wenzhou, Mean (95% CI)
Age, median (25th-75th percentile), y	47 (37-56)
Age group — no./total no. (%)	
<15	5 (1.2)
15-44	179 (41.2)
45-65	202 (46.5)
≥ 65	48 (11.1)
Male sex - no./total no. (%)	228 (52.5)
Exposure history - no./total no. (%)	
Come from Wuhan	168 (38.7)
Wenzhou “Intime Store”	16 (3.7)
Contact with person with COVID-19	198 (45.6)
Unknown exposure history	52 (12.0)
Signs and symptoms - no./total no. (%)	
Fever	323 (74.4)
cough	222 (51.2)
Fatigue	61 (14.1)
Loss of appetite	11 (2.53)
headache	39 (9.0)
Myalgia	25 (5.8)
Rhinorrhea	8 (1.8)
Interval from symptom onset - days	
To hospitalization	6.5±4.2

To hospital discharge	18.5±4.9
R0 - Mean (95% CI)	2.91 (2.35-3.57)
Epidemic Peak Date	March 3-9, 2020
Epidemic Peak Size (95% CI)	538 (534-542)
