29	Abstract
30	Background: To control the spread of Corona Virus Disease (COVID-19),
31	screening large numbers of suspected cases for appropriate quarantine and
32	treatment is a priority. Pathogenic laboratory testing is the diagnostic gold standard
33	but it is time consuming with significant false negative results. Fast and accurate
34	diagnostic methods are urgently needed to combat the disease. Based on
35	COVID-19 radiographical changes in CT images, we aimed to develop a deep
36	learning method that could extract COVID-19's graphical features in order to provide
37	a clinical diagnosis ahead of the pathogenic test, thus saving critical time for
38	disease control.
39	Methods and Findings: We collected 1,065CT images of pathogen-confirmed
40	COVID-19 cases (325 images) along with those previously diagnosed with typical
41	viral pneumonia (740 images). We modified the Inception transfer-learning model
42	to establish the algorithm, followed by internal and external validation. The internal
43	validation achieved a total accuracy of 89.5% with specificity of 0.88 and sensitivity
44	of 0.87. The external testing dataset showed a total accuracy of 79.3% with
45	specificity of 0.83 and sensitivity of 0.67. In addition, in 54 COVID-19 images that
46	first two nucleic acid test results were negative, 46 were predicted as COVID-19

positive by the algorithm, with the accuracy of 85.2%. 47

Conclusion: These results demonstrate the proof-of-principle for using 48 artificial intelligence to extract radiological features for timely and accurate 49 COVID-19 diagnosis. 50

54

### Introduction

The outbreak of atypical and person-to-person transmissible pneumonia 55 caused by the severe acute respiratory syndrome coronavirus 2 (SARS-COV-2, 56 also known as 2019-nCov) has caused a global alarm. There have been more 57 than 500,000 confirmed cases of the Corona Virus Disease (COVID-19) in the 58 world, as of March 26, 2020. According to the WHO, 16-21% of people with the 59 virus in China have become severely ill with a 2-3% mortality rate. With the 60 most recent estimated viral reproduction number (R0), the average number of 61 62 other people that an infected individual will transmit the virus to in a completely non-immune population, stands at about 3.77 [1], indicating that a rapid 63 spread of the disease is imminent. It is crucial to identify infected individuals as 64 65 early as possible for quarantine and treatment procedures.

The diagnosis of COVID-19 relies on the following criteria: clinical 66 symptoms, epidemiological history and positive CT images, as well as positive 67 68 pathogenic testing. The clinical characteristics of COVID-19 include respiratory symptoms, fever, cough, dyspna, and pneumonia [3-6]. However, these 69 symptoms are nonspecific, as there are isolated cases where, for example, in 70 an asymptomatic infected family a chest CT scan revealed pneumonia and the 71 72 pathogenic test for the virus came back positive. Once someone is identified as a PUI (person under investigation), lower respiratory specimens, such as 73 74 bronchoalveolar lavage, tracheal aspirate or sputum, will be collected for pathogenic testing. This laboratory technology is based on real-time RT-PCR 75

and sequencing of nucleic acid from the virus [7,8]. Since the beginning of the 76 outbreak, the efficiency of nucleic acid testing has been dependent on several 77 78 rate-limiting factors, including availability and quantity of the testing kits in the affected area. More importantly, the quality, stability and reproducibility of the 79 detection kits are questionable. The impact of methodology, disease stages, 80 specimen collection methods, nucleic acid extraction methods, and the 81 amplification system are all determinant factors for the accuracy of test results. 82 Conservative estimates of the detection rate of nucleic acid are low (between 83 30-50%) [7,8,9], and tests need to be repeated several times in many cases 84 before they can be confirmed. 85

Radiological imaging is also a major diagnostic tool for COVID-19. The 86 87 majority of COVID-19 cases have similar features on CT images including ground-glass opacities in the early stage and pulmonary consolidation in the 88 late stage. There is also sometimes a rounded morphology and a peripheral 89 90 lung distribution [6,10]. Although typical CT images may help early screening of suspected cases, the images of various viral pneumonias are similar and 91 they overlap with other infectious and inflammatory lung diseases. Therefore, it 92 is difficult for radiologists to distinguish COVID-19 from other viral pneumonias. 93 94 Artificial Intelligence involving medical imaging deep-learning systems has been developed in image feature extraction, including shape and spatial 95

97 proven in feature extraction and learning. CNN was used to enhance low-light

96

5

relation features. Specifically, Convolutional Neural Network (CNN) has been

images from high-speed video endoscopy with the limited training data being
just 55 videos [11]. Also, CNN has been applied to identify the nature of
pulmonary nodules via CT images, the diagnosis of pediatric pneumonia via
chest X-ray images, automated precising and labeling of polyps during
colonoscopic videos, cystoscopic image recognition extraction from videos
[12-15].

There are a number of features for identifying viral pathogens on the basis 104 of imaging patterns, which are associated with their specific pathogenesis [16]. 105 106 The hallmarks of COVID-19 are bilateral distribution of patchy shadows and ground glass opacity in early stages. As the disease progresses, multiple 107 ground glass and infiltrates in both lungs will appear [3]. Theses features are 108 109 quite similar to typical viral pneumonia with only slight differences, which are difficult to be distinguished by radiologists. Based on this, we believed that 110 CNN might help us identify unique features that might be difficult for visual 111 112 recognition.

Hence, the purpose of our study was to evaluate the diagnostic performance of a deep learning algorithm using CT images to screen for COVID-19 during the influenza season. To test this notion, we retrospectively enrolled 1,065 CT images of pathogen-confirmed COVID-19 cases along with previously diagnosed typical viral pneumonia. Our results reported below demonstrate the proof-of-principle using the deep learning method to extract radiological graphical features for COVID-19 diagnosis.

120

# **Methods and Materials**

# 121 **Retrospective collection of datasets.**

122 We retrospectively collected CT images from 259 patients, in which the cohort includes 180 cases of typical viral pneumonia and the other 79 cases 123 from three hospitals with confirmed nucleic acid testing of SARS-COV-2. In 124 addition, we enrolled additional 15 COVID cases, in which first two nucleic acid 125 tests were negative at initial diagnoses. Hospitals providing the images were 126 Xi'an Jiaotong University First Affiliated Hospital (Center 1), Nanchang 127 128 University First Hospital (Center 2) and Xi'an No.8 Hospital of Xi'an Medical College (Center 3). All CT images were de-identified before sending for 129 analysis. This study is in compliance with the Institutional Review Board of 130 131 each participating institutes. Informed consent was exempted by the IRB because of the retrospective nature of this study. 132

### 133 **Delineation of ROIs**

To establish a binary model for distinguishing COVID-19 and typical 134 pneumonia, we drew the Region Of Interest (ROI) as input images for the 135 training cohort and validation cohorts. We sketched the ROI from CT images 136 based on features of COVID-19, such as small patchy shadows and interstitial 137 changes in the early stage, multiple ground glass and infiltrates in both lungs in 138 the progression stage, and delineated the ROIs on the CT images of other 139 typical viral pneumonia such as pseudocavity, enlarged lymphnodes and 140 multifocal GGO as the control. The ROIs were divided into three cohorts: one 141

training cohort (n=320 from Center 1), one internal validation cohort (n=455 142 from Center 1) and one external validation cohort (n=290 from Center 2 and 3). 143 For a ROI, it is sized approximately from 395\*223 to 636\*533 pixels.

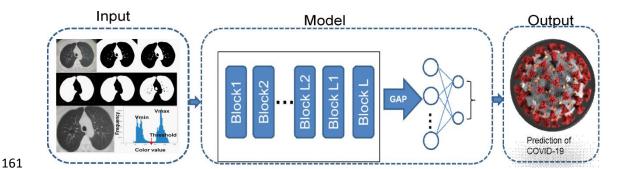

145

144

# Overview of the proposed architecture

Our systematic pipeline for the prediction architecture is depicted in Figure 146 1. The architecture consists of three main processes: 1) Pre-processing of 147 input images; 2) Feature extraction of ROI images and training; and 3) 148 Classification with fully connected network and prediction of multiple classifiers. 149 150 We built a transfer learning neural network based on the Inception network. The entire neural network can be roughly divided into two parts: the first part 151 used a pre-trained inception network to convert image data into 152 153 one-dimensional feature vectors, and the second part used a fully connected network and the main role is for classification prediction. ROI images from 154 each case were preprocessed and inputted into the model for training. The 155 number of various types of pictures in the training set is equal, with a total 156 number of 320. The remaining CT pictures of each case were used for internal 157 validation. The model training was iterated 15,000 times with a step size of 158 0.01. 159

160

**Figure 1**. ROI images extraction and Deep Learning (DL) algorithm framework. ROI images were extracted by the CV model and then trained using a modified Inception network to extract features. The full connection layer then makes a classification and prediction.

166 Image preprocessing and feature extraction.

Based on the signs of characteristic of pneumonia, ROI images were 167 defined inflammatory lesions and extracted by our computer vision (CV) model 168 169 following the steps. 1) Convert the image to grayscale. 2) Binarize grayscale. Because using the OSTU's method directly may cause the threshold selection 170 failure in the case of multi-peaks, the selection of the binarization threshold in 171 this paper was based on the statistics of all pixel frequency histograms of the 172 gray color values Vmin (80) and Vmax (200). The minimum frequency in the 173 selection interval is threshold, and the interval of frequency statistics is five. 3) 174 Background area filling. Using the flood filling method to expand the image by 175 1 black pixel, and fill the black pixels near the border with white. 4) Reverse 176 color, find all the contour areas of the image, and keep the two largest contour 177 areas as the two lung areas. 5) Take the smallest bounding rectangle of the 178 lung area as the ROI frame and crop the original image to obtain the ROI 179

images. The delineated ROIs were obtained for classification model building. 180 We modified the typical Inception network, and fine-tuned the modified 181 Inception (M-Inception) model with pre-trained weights. During the training 182 phase, the original Inception part was not trained, and we only trained the 183 modified part. The architecture of M-Inception is shown in Table 1. The 184 difference between Inception and M-Inception in classification lies in the last 185 fully-connected layers. We reduced the dimension of features before it was 186 sent to the final classification layer. The training dataset made up of all those 187 patches aforementioned. The Inception network is shown in Table 1. 188

190

#### Prediction. 191

192 After generating the features, the final step was to classify the pneumonia based on those features. Ensembling of classifiers was used to improve the 193 classification accuracy. In this study, we adopted end-to-end learning to make 194 the model convergence. 195

#### Performance evaluation metrics. 196

We compared the classification performance using Accuracy, Sensitivity, 197 Specificity, Area Under Curve (AUC), Positive predictive value (PPV), Negative 198 predictive value (NPV), F1 score and Youden Index. TP and TN represent the 199 number of true positive or true negative samples. FP and FN mean the number 200 of false positive or false negative samples. Sensitivity measures the ratio of 201 positives that are correctly discriminated. Specificity measures the ratio of 202 negatives that are correctly discriminated. AUC is an index to measure the 203 performance of the classifier. NPV was used to evaluate the algorithm for 204 205 screening, and PPV was the probability of getting a disease when the diagnostic index is positive. Youden Index was the determining exponent of the 206 optimal bound. F1 score was a measure of the accuracy of a binary model. 207

- Additionally, performance was evaluated with F-measure (F1) to compare the
- similarity and diversity of performance. Kappa value measures the agreement
- between the CNN model prediction and the clinical report.

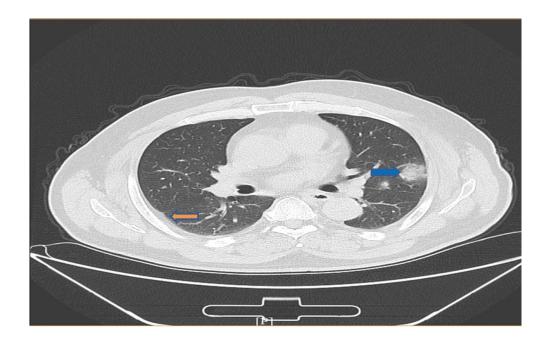

212

### Results

# Algorithm development.

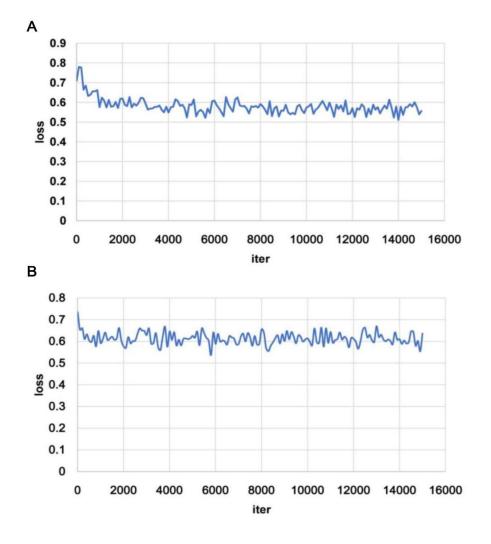

214 In order to develop a deep learning algorithm for the identification of viral pneumonia images, we initially enrolled 259 patients, in which the cohort 215 includes 180 cases of typical viral pneumonia that were diagnosed previously 216 before the COVID-19 outbreak. These patients are termed COVID-19 negative 217 in the cohort. The other 79 cases were from the three hospitals with confirmed 218 nucleic acid testing of SARS-COV-2, therefore termed COVID-19 positive. Two 219 radiologists were asked to review the images and sketched 1,065 220 representative images (740 for COVID-19 negative and 325 for COVID-19 221 positive) for analysis (Figure 2 is shown as an example). These images were 222 randomly divided into a training set and a validation set. The model training 223 was iterated for 15,000 times with a step size of 0.01. The training loss curve is 224 shown in Figure 3A. 320 images (160 images from COVID-19 negative and 225 160 images from COVID-19 positive) were obtained to construct the model. To 226 test the stability and generalization of the model,455 images (COVID-19 227 ngegative 360 images and COVID-19 positive 95 images) were obtained for 228 internal validation from Center 1 and 290 images (COVID-19 negative 220 229 images and COVID-19 positive 70 images) were obtained from Center 2 and 3 230 for external validation. The model training was also iterated for 15,000 times 231 with a step size of 0.01. The training loss curve is shown in **Figure 3B**. 232

233

238

Figure 3. Training loss curves of the models on internal (A) and external (B) validation. The loss curve tends to be stable after descending, indicating that the training process converges

242 **Deep learning performance.** 

The deep learning algorithm yielded an AUC of 0.93 (95% CI, 0.90 to 0.96) on the internal validation and 0.81 (95% CI, 0.71 to 0.84) on the external validation based on the number of CT images (**Figure 4**). Using the maximized Youden index threshold probability, the sensitivity was 0.88 and 0.83,

247	specificity 0.87 and 0.67, the accuracy 89.5% and 79.3%, the negative
248	prediction values 0.95 and 0.90, the Youden indexes 0.75 and 0.48, and the F1
249	scores were 0.77 and 0.63 for the internal and external datasets, respectively
250	(Table 2). The kappa values were 0.69 and 0.48 for internal and external
251	validation, indicating that prediction of COVID-19 from the CNN model is a
252	highly consistent with pathogenic testing results. We also performed an
253	external validation based on each patient's multiple images. The accuracy was
254	82.5%, with the sensitivity 0.75, the specificity 0.86, the PPV 0.69, the NPV
255	0.89, and the kappa value 0.59.

264

261

#### Comparison of AI with radiologist prediction. 265

266 At the same time, we asked two skilled radiologists to assess the 745 images for a prediction. Radiologist 1 achieved the accuracy of 55.8% with 267 sensitivity of 0.71 and specificity of 0.51, and Radiologist 2 achieved a similar 268 accuracy of 55.4% with sensitivity of 0.73 and specificity of 0.50 (Table 3). 269 These results indicates that it is difficult for radiologists to make prediction of 270 COVID-19 with eye recognition, further showing the advantage of the 271 algorithm we developed. 272

279

Prediction of COVID-19 on CT images from pathogenic negative 280 patients. 281

Because high false negative results were frequently reported from nucleic 282 acid testing, we aimed to test whether the algorithm could detect COVID-19 283 when the pathogenic test came negative. To achieve this goal, we enrolled 284 additional 15 COVID-19 cases, in which initial two nucleic acid tests came 285 negative and for the third test they became positive. These CT results were 286 taken on the same day of the nucleic acid tests (Figure 5). Interestingly, we 287 found that, 46 out of the 54 images when nucleic acid test results were 288 negative were predicted as COVID-19 positive by the algorithm, with the 289 accuracy of 85.2%. These results indicate that the algorithm has high value 290 serving as a screening method for COVID-19. 291

292

**Figure 5**. Representative images from a COVID-19 patient with two negatively reported nucleic acid tests at earlier stages and one final positively reported test at a later stage. On the left, only one inflammatory lesion (blue arrow) can be seen near diaphragm. In the middle, lesions (yellow arrows) were found in two levels of images. On the right, the images were taken on the ninth day after admission. The inflammation continued to progress, extending to both lungs (red arrows), and the nucleic acid test became positive.

301

### Discussion

Timely diagnosis and triaging of PUIs are crucial for the control of 302 emerging infectious diseases such as the current COVID-19. Due to the 303 limitation of nucleic acid -based laboratory testing, there is an urgent need to 304 look for fast alternative methods that can be used by front-line health care 305 personals for quickly and accurately diagnosing the disease {Rao, 2020 #67}. 306 In the present study, we have developed an AI program by analyzing 307 representative CT images using a deep learning method. This is a 308 retrospective, multicohort, diagnostic study using our modified Inception 309 migration neuro network, which has achieved an overall 89.5% accuracy. 310 Moreover, the high performance of the deep learning model we developed in 311 312 this study was tested using external samples with 79.3% accuracy. More importantly, as a screening method, our model achieved a relative high 313 sensitivity, 0.88 and 0.83 on internal and external datasets, respectively. 314 Furthermore, the model achieved a performance on the patient level, with the 315 accuracy of 82.5%. During current COVID-19 global pandemics, this CNN 316 model can potentially serve as a powerful tool for COVID-19 screening. 317

It is important to note that our model aims to distinguish between 318 COVID-19 and other typical viral pneumonia, both of which have similar 319 radiologic characteristics. We compared the performance of our model with 320 that of two skilled radiologists, and our model has shown much higher 321 findings accuracy sensitivity. These have demonstrated 322 and the

proof-of-principle that deep learning can extract CT image features of 323 COVID-19 for diagnostic purposes. Using the supercomputer system, the time 324 325 for each case takes only about 10 seconds, and it can be performed remotely via a shared public platform. Therefore, further developing this system can 326 significantly shorten the diagnosis time for disease screening, especially at the 327 time when many places have nucleic acid test shortage. Our study represents 328 the first study to apply artificial intelligence technologies to CT images for 329 effectively screening for COVID-19. 330

331 The gold standard for COVID-19 diagnosis has been nucleic acid based detection for the existence of specific sequences of the SARS-COV-2 gene. 332 While we still value the importance of nucleic acid detection in the diagnosis of 333 334 SARS-COV-2 infection, we must also note that the high number of false negatives due to several factors such as methodological disadvantages, 335 disease stages, and methods for specimen collection might delay diagnosis 336 337 and disease control. Recent data have suggested that the accuracy of nucleic acid testing is only about 30-50% [6,7,8]. Using CT imaging feature extraction, 338 we are able to achieve above 89.5% accuracy, significantly outplaying nucleic 339 acid testing. More interestingly, testing CT images from COVID-19 patients 340 when initial pathogenic testing came negative, our model has achieved the 341 accuracy of 85.2% for correctly predicting COVID-19. According to a study 342 authored by Xia L et al, 75% patients with negative RT-PCR results had 343 positive CT findings [17]. The study also recommended that chest CT as a 344

primary tool for the current COVID-19 detection in affected areas.

Deep learning methods have been used to solve data-rich biology and medicine. A large number of labeled data is required for training [18]. Although we are satisfied with the initial results, we believe that with more CT images included in the training, we will achieve higher accuracy. Therefore, further optimizing and testing this system is warranted. To achieve this, we have generated a webpage that licensed healthcare personnel can access to upload CT images for testing and validation. The webpage information is as following:

353 <u>https://ai.nscc-tj.cn/thai/deploy/public/pneumonia\_ct.</u>

There are some limitations to our study. Although DL has been used to 354 represent and learn predictable relationships in many diverse forms of data, 355 356 and it holds promise for applications in precision medicine, many factors such as low signal to noise and complex data integration have challenged the DL 357 efficacy [19]. CT images represent a difficult classification task due to the 358 359 relatively large number of variable objects, specifically the imaged areas outside the lungs that are irrelevant to the diagnosis of pneumonia [12]. In 360 addition, the training data set is relatively small. The performance of this 361 system is expected to increase when the training volume is increased. It 362 should also be noted that, the features of the CT images we analyzed were 363 from patients with severe lung lesions at later stages of disease development. 364 Although we have enrolled 15 cases of COVID patients for assessing the value 365 of the algorithm for early diagnosis, larger numbers of database to associate 366

this with the disease progress and all pathologic stages of COVID-19 is necessary to optimize the diagnostic system.

In future, we intend to link hierarchical features of CT images to features of other factors such as genetic, epidemiological and clinical information for multi-modeling analysis for an enhanced diagnosis. The artificial intelligence system developed in our study should significantly contribute to COVID-19 disease control by reducing the number of PUIs for timely quarantine and treatment.
