22 **Running title:**

23 *S. pneumoniae* carriage among Colombian children.

24 **Abstract:**

25 *Streptococcus pneumoniae* diseases are important causes of children death worldwide.  
26 Nasopharyngeal carriage of this pathobiont promotes bacterial spread and infections in the  
27 community. Here, a cross-sectional surveillance study was done to determine the proportion of  
28 nasopharyngeal colonization, antimicrobial susceptibility profile and associated factors in  
29 pediatric outpatients (southwestern Colombia, 2019). Data on factors associated with  
30 pneumococcal nasopharyngeal carriage were obtained through survey-based interviews.  
31 Nasopharyngeal swabs were collected and bacteria were microbiologically characterized.  
32 Antimicrobial susceptibility tests were done by VITEK-2. A logistic regression analysis was  
33 performed to examine associated factors. Tests with a *p*-value <0.05 were considered  
34 statistically significant. 452 children from the southwestern Colombia were examined and  
35 41.8% carried *S. pneumoniae*. A higher pneumococcal carriage frequency was observed  
36 among participants <2-years and in individuals belonging to indigenous communities, which  
37 were not immunized against pneumococcus, because of lacking established immunization  
38 schemes. Additionally, children attending child-care institutions were also highly colonized by  
39 pneumococci. *S. pneumoniae* showed 57.7% non-susceptibility to benzyl-penicillin  
40 (meningitis-cut); 45.5% intermediate-sensitivity to benzyl-penicillin (oral-cut) and 21.7% to  
41 cefotaxime; and resistance to erythromycin (40.7%), tetracycline (36.0%),  
42 trimethoprim/sulfamethoxazole (24.9%), clindamycin (24.3%) and ceftriaxone (27.0%). The  
43 proportion of 41.8% of participants carrying *S. pneumoniae* shows a scenario with the presence  
44 of strains resistant to different antimicrobial agents (MDR and XDR), which constitutes  
45 important reservoirs of bacterial transmission by children <5-years in the southwest of  
46 Colombia. This situation could potentially lead to an onset of pneumococcal diseases. Hence,

47 the need to expand conjugate pneumococcal immunization in the community and ensure  
48 compliance with established immunization schedules.

49 **Keywords:**

50 *Streptococcus pneumoniae*; Nasopharyngeal Carriage; Children under 5 Years of Age;  
51 Antimicrobial Susceptibility; Southwest of Colombia.

52 **Introduction:**

53 *Streptococcus pneumoniae*, also known as the pneumococcus, is a Gram-positive bacteria and  
54 a normal inhabitant of the nasopharyngeal microbiota of healthy children under 5 years old. The  
55 colonization process begins shortly after birth. Although pneumococcal carriage is usually  
56 asymptomatic, it can later serve as a reservoir for infections in children, the elderly,  
57 immunocompromised people and individuals with underlying diseases. However,  
58 *S. pneumoniae* is also a severe pathogen capable of causing diseases including community-  
59 acquired pneumonia (CAP), bacteremia, sepsis, meningitis, otitis media and sinusitis (1,2). It is  
60 estimated that diseases caused by this bacterium are a major public health problem worldwide,  
61 due to high morbidity and mortality rates (3). *S. pneumoniae* is the leading cause of lower  
62 respiratory tract infections worldwide, contributing to more deaths than all other etiologies  
63 combined (4). Nearly one million children under the age of 5 die each year due to diseases  
64 caused by the pneumococcus (2).

65 CAP constitutes a significant proportion of hospital admissions and the global burden of disease  
66 in children, being responsible for high mortality rates in infants, mainly in countries with low and  
67 medium incomes (5-9). *S. pneumoniae* is the leading cause of bacterial pneumonia, being  
68 identified in most cases, and is therefore considered a silent killer of children under 5 years of  
69 age (10,11). In Colombia, pneumonia is one of the main causes of mortality with 13 cases

70 100,000 deaths, with *S. pneumoniae* being its main etiological agent with a mortality rate of 3%  
71 (12). Likewise, for *S. pneumoniae* in Colombia, the average incidence is 0.28 cases per /  
72 100,000 inhabitants, with a lethality between 13% and 27%, even with the appropriate treatment  
73 of individuals affected (13,14).

74 The asymptomatic carriage of *S. pneumoniae* has been identified as a prerequisite for the  
75 development of invasive and non-invasive diseases, and the carriers serve as sources of  
76 transmission of *S. pneumoniae* to other individuals in the community and within hospitals (15-  
77 18). Several clinical and demographic characteristics have been positively associated with an  
78 increase in the colonization of *S. pneumoniae*, such as infancy, overcrowding, childcare  
79 assistance, family size, sibling numbers, poverty, smoking and recent use of antibiotics (19-  
80 21). Although nasopharyngeal isolates are not useful for predicting the causative agent of  
81 invasive disease in individuals, they do reflect the epidemiological aspects of diseases caused  
82 by *S. pneumoniae* in the community (22,23). Bacteria inhabiting the upper respiratory tract of  
83 healthy children reflect the strains causing infection that are currently circulating in the  
84 community (24). Studies in the recent decades have gradually revealed the connection between  
85 pneumococcal carriage and invasive, and mucous infections caused by this pathobiont  
86 (15,18,25).

87 For many years, antibiotics such as penicillin and chloramphenicol have been used for the  
88 treatment of pneumococcal disease in low- and middle-income countries, given its  
89 effectiveness and low costs. Unfortunately, the dramatic increase in resistance to these and  
90 other antimicrobial agents worldwide has made the choice of antimicrobial drugs for  
91 *S. pneumoniae* infections increasingly difficult and expensive (28-31). Currently, prevention  
92 campaigns against pneumococcal infections are carried out using pneumococcal-conjugated  
93 vaccines (PCVs), which use the capsular polysaccharides of those specific serotypes most

94 frequently associated with invasive pneumococcal diseases (IPDs) (1,26,27). In Colombia, the  
95 7-valent pneumococcal conjugate vaccine was introduced in 2006 in the National Immunization  
96 Program, and replaced in 2011 by the 10-valent (2+1 doses).

97 The decrease in several primary risk factors, the implementation of better immunization  
98 strategies, and advances in the treatment of pneumococcal infections have made a substantial  
99 progress in recent years in reducing the burden of pneumococcal diseases. However, this has  
100 not been the same in all geographic regions of the world and more research and intervention  
101 efforts are still needed. In addition, nasopharyngeal colonization by antibiotic-resistant  
102 *S. pneumoniae* has been steadily increasing, representing potential dangers for the community  
103 (4,32,33). In Colombia, and particularly in the southwestern region (Departments of Valle del  
104 Cauca, Cauca, Putumayo and Nariño) (Figure 1), epidemiological data on *S. pneumoniae* are  
105 extremely limited. Therefore, the objective of this study was to determine the proportion of  
106 nasopharyngeal colonization, the profile of antimicrobial susceptibility and the possible  
107 associated factors in pediatric outpatients attending the Club Noel Children's Clinical  
108 Foundation. This information will be useful for the implementation of more rational therapeutic  
109 and preventive strategies against pneumococcus in Southwestern Colombia, where the therapy  
110 for pneumococcal disease remains empirical due to the lack of rapid, sensitive and specific  
111 diagnostic tests.

## 112 **2. Methodology:**

### 113 **2.1. Research Context, Population Definition and Inclusion Criteria**

114 This work consisted on a cross-sectional study conducted for the southwestern region of  
115 Colombia (Figure 1), where 452 children under 5 years of age were randomly selected and  
116 prospectively involved in the surveillance in 2019. For convenience and logistical support, all  
117 children under five years of age eligible to participate in the study were those who attended the

118 Club Noel Children's Clinical Foundation of Cali (the main populated center of the Colombian  
119 southwest) and who were evaluated by external consult for pediatric control visits (34–37). The  
120 Club Noel Children's Clinical Foundation is a second level pediatric hospital that operates every  
121 day of the year, serving up to 300 patients per day. Routine functions of the outpatient  
122 department include monitoring of children's growth, immunization, nutritional counseling and  
123 management of ailments. Although the population attending in Club Noel Children's Clinical  
124 Foundation comes mainly from the city of Cali, another large number of pediatric patients come  
125 from other nearby municipalities and departments, causing the study population to become a  
126 mixture of people from different races, and representatives of both urban and rural areas.

## 127 **2.2. Sampling of the Study Population and Exclusion Criteria**

128 The study population of this work was constituted by the pneumococcal colonizing isolates from  
129 the 452 children below 5 years old from the southwest Colombia involved in the investigation.  
130 This sample size was estimated using the general formula for a proportion of a single population  
131 with the following assumptions: 1) A total population of children under 5 years of age in the  
132 Colombian southwest of 734,372 (according to DANE projections as of June 30, 2018, the total  
133 population of the Colombian southwest would correspond to about 16% of the total national  
134 territory (7,981,162 of 49,879,349), of which about 669,400 would be children under 5 years of  
135 age) (38,39); 2) A prevalence rate of nasopharyngeal colonization by pneumococci of 50%  
136 (according to unpublished studies by our research group in the city of Medellin: 55.5%); 3) A  
137 95% confidence level; AND 4) A marginal error or possible loss of information of 20%. The  
138 study participants were randomly associated and involved prospectively until the sample size  
139 was completed. The main exclusion criteria were: 1) Children under 5 years old with invasive  
140 pneumococcal disease diagnosed or critically affected by other diseases such as  
141 bronchopulmonary dysplasia, chronic immunodeficiency, cancer or any other acute, moderate

142 or severe illness; 2) Children who had received antibiotics in the previous month or who had  
143 previously received any immunosuppressive medication such as prednisolone, cyclosporine,  
144 methotrexate, cyclophosphamide, azathioprine, mycophenolate mofetil or 5-fluorouracil; and 3)  
145 Those children whose parents or guardians were unwilling or unable to give their informed  
146 consent freely and spontaneously.

### 147 **2.3. Collection of Clinical and Sociodemographic Information**

148 This minimum risk level study was reviewed and approved by the Bioethics Committee of the  
149 Club Noel Children's Clinical Foundation in Cali - Colombia. Initially, the study was socialized  
150 with parents or guardians of each child, who subsequently accepted the voluntary participation  
151 of their children by signing a written informed consent. Each participant was assigned a code  
152 and only the personnel involved in the investigation had confidential access to the information  
153 in the individual records. Then, the sociodemographic and housing data of the children under  
154 5 years of age participating in the study were collected through a standardized and previously  
155 tested survey, applied to the parents or guardians of each child. The questionnaire of survey  
156 was mainly made up of closed questions that inquired about the date of birth, age, gender, race,  
157 conditions and socioeconomic status of the home, the constitution of the family nucleus, among  
158 others. Likewise, data were collected on the clinical history of the participating children such as  
159 nutritional status, breastfeeding, consumption of antibiotics and other medications, the history  
160 of the diseases suffered, and immunization records grouped into the following categories: not  
161 immunized, incomplete vaccination, vaccination in process (for children <1 year of age), and  
162 complete vaccination (for children > 1 year of age).

### 163 **2.4. Nasopharyngeal Swab and Preservation of Biological Material**

164 Nasopharyngeal swab samples were collected from each child selected to participate in the  
165 study using sterile flexible swabs (Copan, Brescia, Italy), according to standardized procedures.

166 In brief, the swab was introduced through a nostril to the nasopharynx, where it was turned 180  
167 degrees, and then carefully removed. Each swab collected was immediately introduced into a  
168 cryovial with 1 mL of STGG transport medium (skim milk solution - tryptone - glucose - glycerol)  
169 (40,41), for preservation at -30°C in the Microbiology Laboratory of Club Noel Children's Clinical  
170 Foundation. Samples collected each week were transported on dry ice to the Central Research  
171 Laboratory of the School of Microbiology of the University of Antioquia in Medellín, Colombia.

## 172 **2.5 Isolation, Cultivation, Identification and Cryopreservation of Pneumococci**

173 To isolate and cultivate the pneumococcus after arrival of the material to the laboratory, a 10  
174 µL aliquot of the sample was used for growth in tryptic soy agar (TSA) solid medium,  
175 supplemented with defibrinated sheep blood (5%), yeast extract (0.5%) and gentamicin (5  
176 µg/mL). Pneumococci were incubated at 37°C and CO<sub>2</sub> (5%) for a maximum of 24 hours, after  
177 which the following tests and assays were necessary to confirm their identification: 1) Evidence  
178 of Hemolysis (although the pneumococci are catalase-negative bacteria, as α-hemolytic  
179 microorganisms they can cause partial hemolysis due to the oxidation of iron in hemoglobin,  
180 which causes greenish colonies to occur when grown on blood agar plates), 2) Gram staining  
181 (pneumococci are Gram-positive), 3) Optochin sensitivity test (unlike other streptococci and α-  
182 hemolytic microorganisms, pneumococci are sensitive to 5 mg ethylhydrocupreine  
183 hydrochloride / optochin. Isolates with an inhibition zone ≥14 mm in diameter were considered  
184 susceptible to optochin), and 4) Bile solubility test (the pneumococcus is soluble in bile). The  
185 addition of small amounts of bile salts (2% sodium deoxycholate) results in complete  
186 destruction of the pneumococcus after a short incubation period. Finally, stocks were generated  
187 for the storage of the isolates, through the use of Todd-Hewitt supplemented with yeast extract  
188 (THY) liquid culture medium, supplemented with glycerol (25%) in cryovials, which were then  
189 preserved in an ultra-freezer at -80°C (2,41).

## 190 **2.6. Determination of Susceptibility / Antibiotic Resistance (VITEK-2 System)**

191 To test the susceptibility or resistance of the colonizing isolates against different antibiotics,  
192 fresh cultures of *S. pneumoniae* were made on Mueller-Hinton Agar plates, supplemented with  
193 Ram's Blood (5%) and incubated for 14 hours at 37°C and CO<sub>2</sub> (5%). The diluted inoculum was  
194 then prepared in sterile 0.45% saline solution by resuspending the colonies until a turbid  
195 suspension equivalent to that of a McFarland 0.5 standard was obtained. Subsequently,  
196 following the protocols established by the Clinical and Laboratory Standards Institute (42,43),  
197 the identification tests (GP Test Cards for Gram-positive cocci) and antimicrobial sensitivity  
198 (AST03 Cards for Streptococcal Susceptibility) were performed, using the VITEK system -2  
199 from BioMérieux. In short, the AST03 cards were inoculated, filled and inserted into the VITEK-  
200 2 incubator reader device within 15 minutes after the preparation of the inoculum, according to  
201 the manufacturer's instructions. The AST03 susceptibility cards of the VITEK-2 system contain  
202 Wilkins-Chalgren culture medium, modified with the following antimicrobial agents: Benzyl-  
203 penicillin (Meningitis, Oral and Pneumonia), Ceftriaxone (Meningitis and Other), Cefotaxime  
204 (Meningitis and Other), Vancomycin, Erythromycin, Tetracycline, Clindamycin,  
205 Chloramphenicol, Linezolid, Tigecycline, Trimethoprim / Sulfamethoxazole, Levofloxacin,  
206 Moxifloxacin, Rifampicin. The strain ATCC 49619 was used as a pneumococcal control.  
207 According to the CLSI criteria, colonizing pneumococcal isolates were classified as sensitive,  
208 sensitive intermediate or resistant, according to established cut-off points (2,42,43).

## 209 **2.7. Statistical Analysis**

210 The statistical analysis of the data and results obtained in this study was performed as follows:  
211 1) The data were tabulated, validated and analyzed using the Excel® program and the  
212 Statistical Package for Social Sciences (SPSS®) version 20.0 ( IBM Corporation, Chicago, IL,  
213 USA); 2) Descriptive statistics (Univariate Analysis) were performed to summarize the

214 sociodemographic information, the proportions of nasopharyngeal carriage, the molecular  
215 characteristics and susceptibility / antimicrobial resistance of the isolates; 3) Fisher and Chi-  
216 square exact tests (Bivariate Analysis) were carried out to identify the candidate variables for  
217 the multivariate analysis (Hosmer-Lemeshow Criteria, Cut Point  $P < 0.25$ ); and finally, 4) a  
218 logistic regression model (Multivariate Analysis) was made, using the Enter method, in order to  
219 identify possible factors associated with the nasopharyngeal carriage of pneumococci. P values  
220  $< 0.05$  were considered statistically significant.

### 221 **3. Results:**

#### 222 **3.1. Socio-Demographic, Clinical, Housing and Life Habits Characteristics**

223 A total of 452 individuals under 5 years old of southwestern Colombia, who attended the Club  
224 Noel Children's Clinic for outpatient services between September and October of 2019, were  
225 included in this study. From this population, 241 (53.3%) were male and 211 (46.7%) were  
226 female. According to the age, 105 (23.2%) children were under 1 year old, 85 (18.8%) were  
227 one year old, 88 (19.5%) children were two years old, 77 (17.0%) were three years old, 69 (15.3  
228 %) four years, and 28 (6.2%) five years old. The average age of the children was 30 months  
229 with a standard deviation of 18 months. Regarding race or ethnicity, 349 (77.2%) identified  
230 themselves as mestizo-Colombians, 68 (15.1%) declared themselves to be Afro-Colombians,  
231 and 35 (7.7%) recognized themselves as indigenous people belonging to Amerindian  
232 communities settled mainly in the department from Cauca. The majority of children 429 (94.5%)  
233 belonged to socioeconomic strata 1, 2 and 3 (Low/medium-income levels), while two (0.4%)  
234 participants belonged to stratum 6 (high-income level) from the municipalities of Yumbo and  
235 Jamundí. Three hundred ninety-nine (88.3%) participating children came from 21 different  
236 municipalities in the department of Valle del Cauca of which 244 (61.1%) lived in the city of  
237 Cali. Participation of 51 (11.3%) children was obtained from the department of Cauca, while

238 from the department of Nariño no children could be included during the sampling period (Table  
239 1A).

240 Forty-two (9.3%) participating children were clinically diagnosed with severe diseases such as  
241 anemia, cerebral paralysis and hip dysplasia, among others. At some point in their life, 174  
242 (38.5%) children were diagnosed with a respiratory illness such as pneumonia, asthma,  
243 bronchitis, otitis and rhinitis, among others. However, they were fully recovered at the time of  
244 sampling. On the other hand, 267 (59.1%) participants were diagnosed with respiratory signs  
245 and symptoms at the time the samples were collected, such as nasal secretion, cough,  
246 sneezing and phlegm, among others. Regarding the immunization status, 298 (65.9%)  
247 participants had received at least one dose of pneumococcal vaccine, mainly from the biological  
248 10-valent conjugate (99.7%). Only 187 (41.4%) participants certified to have a complete PCV  
249 immunization schedule (2+1 doses) (Table 1B).

250 Regarding the conditions of housing, home and life habits, 51 (11.3%) children participating in  
251 the study lived in overcrowded conditions (3 or more people per bedroom), while 98 (21.7%)  
252 children had their own room and slept without companions in their own bed. Finally, 61 (13.5%)  
253 participants lived with people who smoke cigarettes regularly, while 178 (39.4%) of the children  
254 attended child care institutions near their homes (Table 1C).

### 255 **3.2. Nasopharyngeal carriage of *S. pneumoniae* in Children of the Colombian Southwest**

256 Of the 452 children examined, 189 (41.8%) were carriers of *S. pneumoniae*. The highest  
257 proportion of nasopharyngeal colonization of *S. pneumoniae* was observed in two-year-old  
258 children (41 children, 46.6%). The overall proportion of nasopharyngeal carriage of  
259 *S. pneumoniae* was 105 (43.6%) in males versus 84 (39.8%) in females. Children belonging to  
260 Indigenous communities had the highest proportion of nasopharyngeal colonization (22  
261 children, 62.9%), while the lowest proportion was observed in Afro-Colombian participants (24

262 children, 35.3%). In children with the lowest socioeconomic condition (Stratum 1), the overall  
263 proportion of nasopharyngeal carriage of *S. pneumoniae* was 63 (47.7%). The colonization rate  
264 of children from the department of the Cauca was 58.8% (Table 2A).

265 Having been clinically diagnosed with severe diseases (23, 54.8%), respiratory diseases at  
266 some time in life (79, 45.4%), and respiratory signs and symptoms at the time of sampling (133,  
267 49.8%) were the variables identified with higher proportions of nasopharyngeal colonization by  
268 *S. pneumoniae* than in healthy participants. Likewise, the colonization ratios of children not  
269 immunized (71, 46.1%) or with incomplete immunization schedules (53, 47.7%) were higher  
270 than those children with complete immunization schedule (65, 34.8%) (Table 2B, Figure 1).

271 The proportion of nasopharyngeal colonization of *S. pneumoniae* was 24 (47.1%) among  
272 participants living in overcrowded conditions versus 41 (41.8%) in children who do not share  
273 their room and sleeping alone in their bed. Of the participants living with people smoking  
274 regularly at home, 23 (37.7%) were positive for *S. pneumoniae*. Finally, the proportion of  
275 colonization of children attending child care institutions in the vicinity of their homes (87, 48.9%)  
276 was higher than that of participants not attending any institution (102, 37.2%) (Table 2C).

### 277 **3.3. Analysis of the Factors Associated with the Nasopharyngeal Carriage of** 278 ***S. pneumoniae***

279 The results showed a correlation between pneumococcal colonization and the 2-year age group  
280 (OR = 3.0; 95% CI = 1.0-8.3; p = 0.041). The nasopharyngeal carriage of *S. pneumoniae* was  
281 significantly higher in children belonging to indigenous communities (OR = 2.7; 95% CI = 1.2-  
282 5.9; p = 0.014). In addition, there was a significant association between nasopharyngeal  
283 colonization of *S. pneumoniae* and nasal secretion at the time of sampling (OR = 2.1; 95% CI  
284 = 1.3-3.3; p = 0.003). Failure to complete immunization schedules (OR = 2.5; 95% CI = 1.3-5.0;  
285 p = 0.008) and not having received immunization against pneumococcus (OR = 1.7; 95% CI =

286 1.1-2.8;  $p = 0.028$ ) was significantly associated with the presence of *S. pneumoniae* in the  
287 nasopharynx in southwestern Colombia (Figure 2). Likewise, attending childcare institutions  
288 (OR = 1.8; 95% CI = 1.0-3.2;  $p = 0.042$ ) was significantly correlated with nasopharyngeal  
289 colonization of *S. pneumoniae*. However, there was no significant association between gender,  
290 socioeconomic stratum, severe diseases, respiratory disease at some time in life (asthma,  
291 pneumonia, rhinitis, etc.), respiratory signs and symptoms at the time of sample collection  
292 (cough, sneezing and phlegm, among others), low weight at birth, and overcrowding with the  
293 nasopharyngeal carriage of *S. pneumoniae* (Table 3).

#### 294 **3.4. Antimicrobial Resistance / Susceptibility Profiles of Colonizing Isolations**

295 The resistance / susceptibility profiles to the 18 antibiotics contained in the AST-03 card (VITEK-  
296 2) of the *S. pneumoniae* colonizing isolates identified in this study are reported in Table 4. All  
297 pneumococcal isolates were susceptible to vancomycin, chloramphenicol, linezolid, tigecycline,  
298 levofloxacin, moxifloxacin and rifampicin. Fifty-five (29.1%) *S. pneumoniae* colonizing isolates  
299 were susceptible to all antibiotics tested, 31 (16.4%) were resistant to an antimicrobial agent,  
300 and 26 (13.8%) were resistant to two. Sixty-nine (36.5%) colonizing isolates of *S. pneumoniae*  
301 were resistant to between three and ten different antibiotics (MDR: Multi-Drug Resistant), while  
302 23 (12.2%) presented resistance profiles to at least one antibiotic in each class of antimicrobial  
303 agents (XDR: Extensively-Drug Resistant). 109 (57.7%) *S. pneumoniae* clinical isolates not  
304 susceptible to benzyl-penicillin (cut meningitis) were identified and isolated, and 86 (45.5%)  
305 presented a reduced or intermediate susceptibility to this antibiotic, according to the oral cutoff  
306 threshold. Seventy-seven (40.7%) colonizing isolates of *S. pneumoniae* were resistant to  
307 erythromycin, 68 (36.0%) were resistant to tetracycline, 47 (24.9%) were resistant to  
308 trimethoprim / sulfamethoxazole, and 46 (24.3%) were resistant to clindamycin. Regarding  
309 Ceftriaxone and Cefotaxime (third generation cephalosporin), 51 (27.0%) and 41 (21.7%)

310 isolates of *S. pneumoniae* were identified with resistance profiles and intermediate  
311 susceptibility, respectively.

312 **Discussion:**

313 In this study, a nasopharyngeal carriage rate of *S. pneumoniae* in children under 5 years of  
314 41.8% was observed for the first time in Colombia. These results are in accordance with the  
315 high frequencies of colonization observed by our research group in other cities of the country,  
316 such as Medellín, where it has been possible to observe a colonization of 55.5% (unpublished  
317 data). Other surveillance studies conducted in other countries have reported similar carriage  
318 rates (17,35,37,44). This may, nevertheless, suggest that the Colombian southwest has a large  
319 number of children belonging to low socioeconomic strata, carriers of *S. pneumoniae*, with a  
320 high risk of developing invasive and non-invasive pneumococcal diseases. Consequently, they  
321 represent a transmission reservoir, not only for members of their families (other children and  
322 older adults), but also for their childhood partners with whom they interact in the community,  
323 especially in institutions where care is provided (45). In our study, children belonging to the age  
324 group of 2 years were identified with highest carriage rate (41: 46.6%), which coincides with  
325 the times when parents begin their children's schooling in this region of the country. Likewise,  
326 participants who said they belonged to indigenous communities were the most vulnerable to  
327 the nasopharyngeal presence of *S. pneumoniae* (22: 62.9%), which also contributed to a  
328 colonization rate well above the average for the department of Cauca (30: 58.8%). These  
329 results coincide with reports from countries with similar conditions to those in this Latin  
330 American region (23,46-50). However, in children 3, 4 and 5 years of age, a non-significant  
331 decrease in the proportion of colonization by *S. pneumoniae* was observed, which could be the  
332 reflection of the gradual acquisition of mucosal immunity from the respiratory tract superior,  
333 especially in children with complete conjugate immunization schemes against pneumococcus,

334 and reduced exposure to the pathogen in nurseries and their homes. These findings confirm  
335 that children under 2 years of age have a higher risk of acquiring *S. pneumoniae* and suffering  
336 from their diseases, compared to the older age groups (3, 4 and 5 years).

337 Various studies worldwide have described several sociodemographic characteristics  
338 associated with an increase in nasopharyngeal carrying of *S. pneumoniae*, which includes low  
339 birth weight, overcrowding, sleeping with parents or other family members, and the fact of living  
340 with people who smoke regularly (15). However, in our study, none of these factors was  
341 associated with nasopharyngeal colonization of *S. pneumoniae*. On the contrary, other factors  
342 such as environmental and / or host factors (underlying diseases, immunosuppression, etc.)  
343 could be the main determinants of the distribution of the carriage among the children of the  
344 Colombian southwest participating in this study. In addition to age and ethnicity, in the logistic  
345 regression analysis, colonization rates for *S. pneumoniae* were significantly associated with  
346 nasal secretion at the time of sampling, and with not being immunized against pneumococcus  
347 or having the incomplete immunization schedule (2 + 1) (Figure 2) (3,18). Regarding the  
348 environmental factor, children attending childcare institutions showed a significantly greater  
349 nasopharyngeal colonization of *S. pneumoniae* compared to children who were not in school.  
350 These results are similar to those found by our research group in children attending school in  
351 the city of Medellín and to reports from countries with similar conditions (51–53). This finding is  
352 of great relevance because exposure to other children during childhood, especially peers in  
353 community care institutions, has been clearly associated with an increased risk of colonization  
354 and invasive and non-invasive pneumococcal disease.

355 The results of the susceptibility study revealed higher antibiotic resistance of *S. pneumoniae* to  
356 relatively cheap and readily available antibiotics for the population such as benzyl-penicillin cut  
357 meningitis (57.7%), erythromycin (40.7%), tetracycline (36.0%) and

358 trimethoprim/sulfamethoxazole (24.9%), and more expensive but of variable use alternatives  
359 such as ceftriaxone (27.0%) and clindamycin (24.3%). This observation is consistent with  
360 previous reports in Venezuela and other countries of the world (33,54-58). On the other hand,  
361 vancomycin, chloramphenicol, linezolid, tigecycline, levofloxacin, moxifloxacin and rifampicin  
362 were the most effective antibiotics against *S. pneumoniae* isolates, all with 100% antimicrobial  
363 susceptibility, which is consistent with reports from other countries of the region (30,33,59).  
364 Twenty-three (12.2%) colonizing isolates of *S. pneumoniae* presented resistance profiles to at  
365 least one antibiotic in each class of antimicrobial agents, which includes them in the dangerous  
366 group of extensively drug-resistant pneumococci (XDR). Likewise, 69 (36.5%) isolates were  
367 resistant to between three and ten different antibiotics, being considered in this study as multi-  
368 drug resistant *S. pneumoniae* (MDR). Less than 1/3 of the pneumococci isolated in  
369 southwestern Colombia were susceptible to all antibiotics tested, which is a direct product of  
370 frequent and inappropriate use of the chemotherapeutics. Although data on the use of different  
371 antibiotics in low- and middle-income countries are underrepresented, the rates of resistance  
372 of pneumococci to antimicrobial agents vary according to geographic region and the different  
373 population subgroups analyzed (31,34,60). These variations represent major challenges for  
374 health systems in Latin American countries and reflect the uncontrolled and low-cost availability  
375 of some of these medical resources (30). This phenomenon is not foreign to Colombia and its  
376 southwestern region (14.61–63), which would be exerting greater selection pressure for  
377 resistant *S. pneumoniae* strains, favoring the increase in their frequency and, therefore,  
378 decreasing the efficacy of these antibiotics in the treatment of *S. pneumoniae* affected patients.

### 379 **Conclusions:**

380 In this study, a general proportion of nasopharyngeal colonization of *S. pneumoniae* of 41.8%  
381 is reported for the southwestern region of Colombia, with a higher frequency among 2-year-old

382 participants. Belonging to Native American (indigenous) communities, not being immunized  
383 against pneumococcus, not completing established immunization schemes, attending  
384 child-care institutions, and presenting nasal secretion are risk factors for nasopharyngeal  
385 carrying of *S. pneumoniae* in this region of the country. On the other hand, a non-susceptibility  
386 of *S. pneumoniae* to benzyl-penicillin (meningitis and oral cuts), increased resistance to  
387 antibiotics erythromycin, tetracycline, trimethoprim/sulfamethoxazole and clindamycin was  
388 observed, in addition to resistance and intermediate levels of susceptibility to cephalosporin of  
389 broad spectrum (ceftriaxone and cefotaxime). In conclusion, with this study the local and  
390 regional frequency data of children under 5 years of age carrying *S. pneumoniae* is obtained  
391 for the southwest of Colombia for the first time. This high proportion of children carrying  
392 *S. pneumoniae* could show an important reservoir of bacterial transmission among children  
393 under 5 years of age in that community, which could potentially lead to the onset of  
394 pneumococcal diseases with serious consequences for the health of people in this Colombian  
395 region. Therefore, there is a clear need to expand pneumococcal conjugate immunization in  
396 the community and ensure compliance with established immunization schedules. Additionally,  
397 the determination of the association of nasopharyngeal colonization of resistant MDR and XDR-  
398 like strains with the development of invasive infection by resistant strains is important to  
399 establish rational treatments for the alleged *S. pneumoniae* infections in southwestern  
400 Colombia.
