Abstract

As many federal and state governments are starting to ease restrictions on non-pharmaceutical interventions (NPIs) used to flatten the curve, we developed an agent-based simulation to model the incidence of COVID-19 in King County, WA under several scenarios. While NPIs were effective in flattening the curve, any relaxation of social distancing strategies yielded a second wave. Even if daily confirmed cases dropped to one digit, daily incidence can peak again to 874 cases without import cases. Therefore, policy makers should be very cautious in reopening society.

I. Introduction

The novel coronavirus (COVID-19) pandemic is causing significant death tolls, economic losses and disruptions to the American society. As many parts of the U.S. are flattening the curve to control the current outbreaks and maintain hospital capacities through a combination of non-pharmaceutical interventions (NPIs) and expanded testing, the federal and many state governments are starting to coordinate efforts to ease restrictions and eventually end the lockdown. This project aims to explore the feasibility of gradually relaxing social-distancing orders when a vaccine is not yet available. Focusing on a large urban area (King County, WA), we simulated the outcomes of various opening-up scenarios for one year since the first infection started. This research will provide guidance for state and local governments in implementing policy changes regarding to lockdowns.

II. Methods

Model overview

We developed an agent-based simulation based on the open-source model FRED (a Framework for Reconstructing Epidemic Dynamics)¹. Our current UWFRED model considered King County's population distribution and daily contact pattern, COVID-19 transmission using SEIR model, current NPIs and was simulated for 365 days. We estimated new infection per day to measure the effects of easing social-distancing restrictions.

Baseline assumptions include:

- First infection in King County occurred on January 15th, 2020. Although the man lived in Snohomish County, he commuted to Seattle and thus might have impact on King County². We also assumed this is the only non-local transmission. All other transmissions are community transmissions in King County.
- We divided patients into non-severe and severe groups. We assumed asymptomatic and mild symptomatic patients show similar patterns and considered them as non-severe cases. Severity of symptom depends on age³, and degree of severity does not influence infectivity.
- We assumed full immunity for people who recovered from COVID-19.

Calibration procedure

We calibrated model parameters including COVID-19 transmissibility, daily contact patterns in household, neighborhood, school, and workplace, and probability of staying home when sick, targeting the basic reproduction number (R_0) of COVID-19 which is known to be 2 to 3⁴. We used Latin hypercube sampling to form 1,000 candidate parameter sets. For each parameter set, we replicated the epidemic simulation 50 times to consider stochasticity of the simulation. After selecting the best calibrated parameter sets based on a goodness-of-fit criterion, we clustered them using complete linkage and Euclidean distance method to group results, determining six representative parameter sets (see Appendix 1).

Interventions

We modeled three most common NPIs in the U.S. See Table 1.

Table 1. Simulated NPIs in King County

Policy	Target	Period	Changes in contact pattern (among complied)	Compliance rate
Case isolation at home ¹	Infected individual	onset of symptom +1 day ~ until recovery	50% reduction in household contact No school, workplace, neighborhood contact	Non-severe: default calibrated probability for stay home when sick + 10% Severe: 100%
School closure	Students	3/12~ 8/31	No school contact	100%
Social distancing ²	Entire population	Differs by scenario	Same school/household contact No workplace contact No neighborhood contact	30% - Low 60% - Medium 90% - High

1. When 'case isolation at home' is activated, we assumed that people would reduce household contact and 10% more people stay home in non-severe case compared to the calibrated probability for staying home in King County. We assumed this intervention is effective from 02/28/2020, at the time which the first positive result in King County was announced to the public.
2. Each person and workplace comply to social distancing orders based on their default compliance rate. When a government issues a social distancing order, we categorized it as low, medium, and high. We assumed a percentage of workplace will remain closed and the same amount of people will not have neighborhood contact. The percentage is 30% for low, 60% for medium, and 90% for high orders.

Other possible NPIs, such as contact tracing and voluntary home quarantine, were not considered as they were either not being practiced in large scale in King County, or current social distancing already reflects such interventions.

Scenarios for ending lockdowns

We simulated combinations of eight different levels of social distancing strategies that could be practiced after May 4th, the current final date of Washington government's "Stay Home, Stay Healthy" emergency order, and a 'do nothing' scenario. We set interventions before May 4th based on Washington state orders (Appendix 4). As extending school closure to the next school year is practically difficult, we assumed schools will reopen in September. See Table 2 and Figure 1.

Table 2. Scenarios

Intervention Scenarios	May 5th ~ June 4th	June 5th ~ Aug 31th	Sep 1st ~ End
0	No Intervention		
1	High	Medium	Low
2	High	Medium	No
3	High	Low	Low
4	High	Low	No
5	Medium	Medium	Low
6	Medium	Medium	No
7	Medium	Low	Low
8	Medium	Low	No

Figure 1. Diagram of Simulated Scenarios

III. Results

Calibration result

Out of 1,000 Latin hypercube parameter sets, 58 sets targeted R_0 between 2 to 3. After clustering, six clusters had high similarity and low distance level (Appendix 1). Therefore, for each scenario, we used the centroid of the clusters and replicated 50 times for each centroid, totaling 300 simulations per scenario.

Scenarios outcomes

Comparing Scenario 0 to Scenarios 1-8 shows that NPIs activated on mid-March were effective in flattening the curve and lowering total infection. As expected, Scenario 1, the most powerful and long-lasting social distancing, was most effective in reducing total infections from 41% to 15% of the population, compared to Scenario 0. New incidence peaked on March 18th in Scenario 0 with 37,304 newly infected persons whereas other scenarios peaked on March 11th, with 18,881 persons. The ranking by effectiveness in reducing transmission is Scenario 1, 2, 5, 3, 6, 4, 7, 8, 0. See Figure 2.

Figure 2. Simulated Scenarios Projections

However, Scenarios 1 to 8 all yielded a second wave. Even in Scenario 1, the best case, whose daily new infection dropped to 2 on June 4th and remained around 20 per day until August, as soon as the social distancing strategies were relaxed and school opened, its incidence peaked again to 874 cases per day without import cases. It is noteworthy to look at the total infection since May 4th for Scenarios 2 and 5. Although Scenario 2 totally reopened society from September 1st, the total infection is similar to Scenario 5 which retained low social distancing from September until the end of the simulation. This implies that extending one more month of strong social distancing until June 4th could be as effective as retaining low social distancing in September. See Figure 3.

In addition, the infections by place in Scenarios 1 and 2 (Figure 4) suggest that when social distancing is totally relaxed, peak workplace infection would double and neighborhood infection would more than triple compared to a low level of social distancing.

Figure 3. Projected Second Waves

Figure 4. New Infections by Place

IV. Conclusion

While reopening society is important in revitalizing economy, policy makers should be very cautious in reopening even if daily confirmed cases decrease to one digit or even zero due to low reporting rate.

The main limitation of this model is that in early transmission, daily incidences are much higher than reported cases. However, considering low reporting rate (12%) for symptomatic cases in the U.S.⁵ especially until March, and COVID-19's high prevalence in asymptomatic and mild cases⁶, the numbers might not be too much of an overestimate of the true incidence. In addition, we did not consider hospitalization and fatality as we focused on disease transmission. Considering 100% of severe patients self-isolate at home with only reduced contact in household, we assumed that the intervention performed similarly to hospitalization or death in terms of reducing disease transmission.

2. Simulation results by scenario and parameter cluster

3. COVID-19 Simulation Input Parameters

Parameter name	Value	Unit	Source	Notes
Start date	2020-01-15	-	[2]	
Seed (patient 0)'s age	35	age		
Patient 0's isolation delay	4	day		
Probability of symptoms	1	probability	[7]	There are few reports of laboratory-confirmed cases who are truly asymptomatic. In the model, we assume all infected persons have symptoms, which include non-severe (asymptomatic, mild) and severe symptoms.
Asymptomatic infectivity	1	multiplier	Assume	We assume asymptomatic persons have the same infectivity as symptomatic persons.
Age group cutoffs for symptom severity	15, 50, 65, 120	age	[3]	
Probability of severe symptoms by age group	0.058, 0.120, 0.175, 0.288	probability	[3], [13]	For example, age younger than 15 has 5.8% probability of having severe symptoms and age between 15 and 49 has 12% probability of having severe symptom.
Incubation period distribution	Lognormal with median of 5.10 and dispersion of 1.52	distribution	[8]	
Symptomatic period	13	day	[9]	
Pre-Symptomatic period	1	day	[9], [10]	
Infectious period	14	day	[9], [10]	We assume symptom starts one day after entering the infectious period. All asymptomatic cases are assumed to be non-severe symptomatic cases.
Infectivity*	1, 1, 0.94, 0.69, 0.50, 0.37, 0.27, 0.20, 0.14, 0.11, 0.08, 0.06, 0.04, 0.03	probability	[9], [10]	Each number in the vector corresponds to one infectious day.

* Various literature shows peak infectivity occurring in the first few days, before symptom onset starts. Therefore, we assumed full infectivity for the first two days. Infectivity decreases from 1 to 0 during the rest of the infectious period according to a sigmoid curve¹.

The SEIR structure is shown in the following figure¹²

We simulated disease transmission following the procedure in FRED¹.

- a. In places other than household, for an infectious person i , the expected number of contact to transmit the disease to is:

$$\text{Contact_count} = \text{contacts_per_day}(\text{calibrated, by place}) * \text{transmissibility}(\text{calibrated}) * \text{infectivity}(i)$$

For each contact j in Contact_count, the person j will get infected if fully susceptible. If the Contact_count is not integer, it is randomly rounded.

- b. If the place is household, pairwise transmission is simulated. For an infectious person i 's household member j , if the member is susceptible:

$$\text{Infection_prob} = \text{contact_prob}(\text{calibrated}) * \text{transmissibility}(\text{calibrated}) * \text{infectivity}(i) * \text{susceptibility}(j)$$

If (Random number) < Infection_prob, the person j is infected.

4. Timeline of Washington state orders¹¹

Date	Day	Notes
1/15/20	0	First positive man in Snohomish County arrived Seattle-Tacoma airport
2/28/20	44	First positive result in King County announced to public
3/4/20	49	Recommend work from home
3/11/20	56	Banned gatherings of more than 250 people
3/12/20	57	Closure of all schools
3/15/20	60	All entertainment and recreational facilities, including gyms, bars, and restaurants should close; however, restaurants will be allowed to do take-out and delivery
3/23/20	68	Stay home, stay healthy in place order (through May 4)
