ABSTRACT

Due to the ongoing coronavirus disease (COVID-19) pandemic, there are concerns that patients may be avoiding care for emergent and urgent health conditions due to fear of contagion or as an unintentional consequence of government orders to postpone “non-essential” services. We therefore sought to evaluate the effect of the COVID-19 pandemic on the number of patient encounters for select emergent or urgent diagnoses at a large tertiary-care academic medical center in Boston. Inpatient diagnoses included acute myocardial infarction (MI) and stroke, and outpatient but urgent diagnoses included new referrals for breast and hematologic malignancies. For each condition, we used a “difference-in-differences” approach to estimate the proportional change in number of encounters during the pandemic (March – April 2020) compared with earlier in the same year (January – February 2020), using equivalent periods in 2019 as a control. After the onset of the pandemic, we observed significant reductions in hospitalizations for MI (difference-in-differences estimate, 0.67; 95%CI, 0.46-0.96; $P=0.04$) and stroke (difference-in-differences estimate, 0.42; 95%CI, 0.28-0.65; $P<0.001$) (Table). In the ambulatory setting, there was a reduction in referrals for breast cancer and hematologic cancers, but this did not reach statistical significance until the month after the onset of the pandemic. Our findings suggest an urgent need for public health messaging to ensure that patients continue to seek care for acute emergencies. In addition, decisions by health systems regarding when to reinstate non-emergent care should carefully factor in the harms of delayed diagnosis and treatment occurring during the COVID-19 pandemic.

MANUSCRIPT

Background

In early March 2020, the number of confirmed cases of novel coronavirus disease (COVID-19) in Massachusetts began increasing rapidly. In response to the spread, Massachusetts declared a state of emergency on March 10, 2020. Five days later, the Massachusetts Department of Public Health directed all hospitals and ambulatory surgical centers to postpone or cancel any nonessential procedures to focus the use of healthcare resources on pandemic response and conserve personal protective equipment.¹ Although life-sustaining interventions are explicitly excluded from the order, patients may not be able to distinguish between elective and urgent or emergent problems, and may defer necessary care due to fear of contagion.

Objective

We therefore sought to evaluate the effect of the COVID-19 pandemic on the number of patient encounters for select emergent or urgent diagnoses at the Beth Israel Deaconess Medical Center, a large tertiary-care academic medical center in Boston.

Methods and Findings

We selected conditions for which all patients would be expected to seek care under normal circumstances. Inpatient diagnoses included acute myocardial infarction (MI) and stroke, and outpatient but urgent diagnoses included new referrals for breast and hematologic malignancies. We included breast cancer as it is a common malignancy diagnosed by screening procedures and hematologic cancers as they typically present with mild symptoms yet require urgent treatment. For each condition, we used a “difference-in-differences” approach to estimate the proportional change in number of encounters during the pandemic (March – April 2020) compared with earlier

in the same year (January – February 2020), using equivalent periods in 2019 as a control.

Because the effect on referrals for new malignancies may be delayed (as they would be expected to occur after a decline in primary care clinic visits and screening tests), we performed a sensitivity analysis including a 1-month lag for the oncology referrals. As these analyses used de-identified count data collected as part of a systemwide quality improvement initiative, the institutional review board at Beth Israel Deaconess Medical Center deemed the project not to constitute human subjects research.

After the onset of the pandemic, we observed significant reductions in hospitalizations for MI (difference-in-differences estimate, 0.67; 95%CI, 0.46-0.96; $P=0.04$) and stroke (difference-in-differences estimate, 0.42; 95%CI, 0.28-0.65; $P<0.001$) (Table). In the ambulatory setting, there was a numerical decline in new oncology referrals starting March 1, 2020, but these did not achieve statistical significance in the base-case analysis. However, in lag analyses that examined the effect on cancer diagnoses starting April 1, 2020, there was a significant reduction in referrals for breast cancer (difference-in-differences estimate, 0.35; 95%CI, 0.21-0.58; $P<0.001$) and hematologic cancers (difference-in-differences estimate, 0.39; 95% CI, 0.22-0.68; $P<0.001$).

Discussion

We found a marked decline in presentations for emergent cardiovascular conditions during the pandemic. Reductions in MI during the pandemic have also been observed in Italy,² and for ST-elevation MI in the US,³ but reductions in stroke have not been described before. This decline may be partially due to a true reduction in incident events due to factors such as altered lifestyle and improved air quality during the lockdown. However, Massachusetts has experienced a large increase in at-home mortality during the COVID-19 pandemic, raising concern that people may be deferring necessary care out of fear of contagion, and possibly dying at home.⁴ Furthermore,

short-term lifestyle changes cannot explain the decline in referrals for new diagnoses of malignancies observed in our study, which are likely the result of decreased outpatient cancer screening during this period, due to postponement of in-person primary care visits and screening studies, and delayed referrals.⁵ Given the time-sensitive nature of initiating treatment for these and other life-threatening conditions, urgent efforts are needed to improve public health messaging to ensure that patients continue to seek care for acute emergencies. In addition, decisions by health systems regarding when to reinstitute non-emergent care should carefully factor in the harms of delayed diagnosis and treatment occurring during the COVID-19 pandemic.

DATA AVAILABILITY STATEMENT

All encounter data used in the analyses are presented in the Table.

Table. Results. Changes in Encounters per Day Associated with the COVID-19 Pandemic**A. Base-Case Analysis (Assuming No Lag)**

		January-February		March-April [†]		IRR, [‡]	Difference-in-Differences Estimate, [§]	
Condition	Year	Number of encounters	Incidence rate,* encounters per day (95% CI)	Number of encounters	Incidence rate,* encounters per day (95% CI)	March-April compared with January-February (95% CI)	Ratio of IRR in 2020 to IRR in 2019 (95% CI)	p-value
Hospitalizations for Acute Cardiovascular Conditions								
Myocardial Infarction								
	2019	141	2.39 (2.07-2.76)	93	2.02 (1.69-2.42)	0.85 (0.67-1.07)	0.67 (0.46-0.97)	0.04
	2020	111	1.85 (1.57-2.18)	48	1.04 (0.81 -1.34)	0.56 (0.42-0.76)		
Stroke								
	2019	114	1.81 (1.52-2.16)	74	2.11 (1.70-2.63)	1.17 (0.88-1.55)	0.42 (0.28-0.65)	<0.001
	2020	153	2.43 (2.09-2.83)	42	1.20 (0.90-1.60)	0.49 (0.36-0.68)		
Referrals for New Cancer Diagnosis								
Breast Cancer								
	2019	42	0.72 (0.45-1.12)	48	0.79 (0.52-1.20)	1.11 (0.59-2.05)	0.68 (0.28-1.65)	0.39
	2020	49	0.82 (0.54-1.24)	36	0.61 (0.37-0.99)	0.75 (0.39-1.42)		
Hematologic Cancer								
	2019	77	1.31 (0.92-1.85)	81	1.33 (0.94-1.87)	1.02 (0.62-1.66)	0.69 (0.33-1.46)	0.34
	2020	72	1.20 (0.84-1.73)	50	0.85 (0.55-1.31)	0.71 (0.40-1.24)		

B. Sensitivity Analysis (Assuming a One-Month Lag for Referrals for New Cancer Diagnoses)

Condition	Year	January-March		April		IRR, [†] April compared with January-March (95% CI)	Difference-in- Differences Estimate, [‡] Ratio of IRR in 2020 to IRR in 2019 (95% CI)	p- value
		Number of encounters	Incidence rate,* encounters per day (95% CI)	Number of encounters	Incidence rate,* encounters per day (95% CI)			
Breast Cancer	2019	66	0.73 (0.63-0.85)	24	0.80 (0.63-1.02)	1.09 (0.82-1.44)	0.35 (0.21-0.58)	<0.001
	2020	76	0.84 (0.73-0.96)	9	0.32 (0.22-0.48)	0.38 (0.25-0.58)		
Hematologic Cancer	2019	111	1.23 (1.04-1.46)	47	1.57 (1.21-2.03)	1.27 (0.93-1.73)	0.39 (0.22-0.68)	<0.001
	2020	106	1.16 (0.98-1.38)	16	0.57 (0.37-0.89)	0.49 (0.31-0.79)		

* The incidence rate was estimated by dividing the number of encounters in a given time period by the number of days in the time period; the 95% confidence interval (CI) was constructed by fitting a Poisson regression model with the dispersion parameter estimated by deviance

[†] The most recent data available varied by condition in the year 2020: April 6th for stroke, April 15th for myocardial infarction, and April 28th for malignancies. Events were censored at these dates for both 2019 and 2020 data to ensure equal ascertainment between years.

[‡] Incidence rate ratio (IRR) was calculated from a Poisson regression comparing the number of encounters in the subsequent period (e.g., March-April) in a given year to the number of encounters in the prior period (e.g., January-February).

§ The difference-in-differences estimate is the ratio of the IRR in 2020 to the IRR in 2019 and can be interpreted as the proportional reduction in events during the pandemic, adjusted for prior trends.
