Abstract

Aims: To make time series analysis on the 29-year (1985–2014) trends in height among Han Students Aged 7-18 in China and predict their future height from the perspective of interdisciplinary studies of demography and physical education.

Methods: The data were from the findings of seven cross-sectional surveys from the Chinese National Survey on Students' Constitution and Health (CNSSCH). The mean, standard error, variance analysis, trend test, F test, T test, development growth and growth rate were used to make a descriptive analysis of height trends.

22 The ARIMA model in the time series analysis was applied to predict the height
23 development of Han students in 2024.

24 **Results:** The height of students aged 7-18 substantially increased from 1985 to 2014.

25 The mean of the height of boys increased by 3.99 cm, 8.01 cm, 8.31 cm, 8.63 cm,
26 9.81 cm, 11.62 cm, 10.38 cm, 9.22 cm, 7.50 cm, 5.59 cm, 4.51 cm, and 3.79 cm,
27 respectively. The mean of the height of girls increased by 6.66 cm, 7.36 cm, 8.00 cm,
28 8.84 cm, 9.60 cm, 8.66 cm, 5.57 cm, 4.65 cm, 3.95 cm, 3.32 cm, 2.87 cm and 3.32
29 cm, respectively. The increasing disparity of the sex differential in the mean height
30 was also observed. From 1985 to 2014, the mean of height difference between boys
31 and girls aged 7-18 had been increased constantly. Their mean height differences
32 were 3.27 cm, 4.03 cm, 4.64 cm, and 5.13 cm, respectively in 1985, 1995, 2005, and
33 2014. A narrowing of the urban–rural differential in the mean height was observed. In
34 1985, on average, urban boys aged 7-18 were 4.18cm higher than rural boys in the
35 same age group. And the height differences between urban and rural boys in the
36 same age group were 3.58 cm, 3.18 cm and 2.41 cm, respectively in 1995, 2005 and
37 2014. According to comparison results, the mean height of urban girls was greater
38 than that of rural girls, and the height difference between urban and rural girls had
39 been constantly narrowed as well. The results of 4 comparisons showed that the
40 height differences between urban and rural girls were 3.68 cm, 3.12 cm, 2.62 cm,
41 and 1.98 cm, respectively.

42 **Conclusions:** There was a general increase in the height of Chinese Han students
43 aged 7-18 in the past 29 years and difference between sex, rural-urban and age
44 have been observed. In 2024, the height of students will continue to grow.

45 Introduction

46 The Chinese National Survey on Students' Constitution and Health (CNSSCH)
47 was organized and implemented by the Ministry of Education for 7 times from
48 1985 to 2014, involving 4 aspects: body shape, physical function, physical quality
49 and physical condition. In the 29 years of surveillance on students' constitution
50 and health, test indicators of physical functions and health had changed a lot, but
51 the test instruments, methods and technical specifications of the body shape
52 indicators changed little, and the tests had a relatively high degree of
53 standardization. Therefore, the data has good consistency and high research
54 values.

55 Body shape refers to the shape characteristics of the internal and external parts
56 of the human body and, to a certain extent, reflects the level of physical development,
57 physical function and physical quality of people. It is an important index in the
58 constitution test. And the height is the most representative index in the shape
59 development process [1]. The height of boys and girls is a hot topic in physical
60 education, preventive medicine, hygiene, and pediatrics. In this research, height
61 indexes of Chinese Han students aged 7-18 in the period from 1985 to 2014 were
62 analyzed to discuss their development characteristics and laws, and the AMIRA
63 model was used to predict their height development trend in 2024. Taking height
64 indexes in the constitution test as an entry point, this research tried to use new
65 methods and new ideas to analyze related data of the constitution test and helped to
66 deepen the longitudinal development of constitution and health research in China.

67 **Methods**

68 **Data sources**

69 The data were obtained from the Chinese National Survey on Students'
70 Constitution and Health (CNSSCH), which has been conducted in China since
71 1985. In the seven surveys, there were 471,115 in 1985, 140,633 in 1991,
72 249,492 in 1995, 216,681 in 2000, 291,604 in 2005, 215,319 in 2010, and 214,359
73 in 2014, respectively, the ratio of boy: girl or urban: rural was approximately 1:1 in
74 each [2-8].

75 **Measurements**

76 The mean, standard error, variance analysis, trend test, F test, T test,
77 development growth and growth rate were used to make a descriptive analysis of
78 height development trends. The time series analysis was applied to predicting the
79 height indexes of Han students aged 7-18 in 2024.

80 Firstly, urban and rural indexes were based to calculate the national indexes.
81 The mean, standard deviation, and sample size as relevant urban and rural indexes
82 were known and based to calculate the mean values of height indexes for the
83 National Han students aged 7-18 in 1985, 2000, and 2014.

84 Secondly, a variance analysis and trend test were made on the height indexes of
85 nationwide students in China.

86 Thirdly, pairwise year-based t-tests were made of height indexes of Han
87 students aged 7-18 in 1985, 1995, 2005 and 2014. The t-test method was adopted
88 when the variance was homogenous, while the Satterthwaite t' test was used when

89 the variance is not homogenous.

90 Fourthly, dynamic analysis indexes for the height of Han students aged 7-18 in
91 the period from 1985 to 2014 were calculated [2].

92 1. Growth of the development level

93 Growth is the difference between the levels of development in two different
94 periods in the time series. The calculation formula for the growth is:

95 Growth = the development level of the report period - the development level of
96 the base period.

97 (1)The period-by-period growth is the growth calculated by taking the previous
98 period as the base period in the time series, that is, $a_1 - a_0$, $a_2 - a_0 \dots$, $a_n - a_0$.

99 (2) Cumulative growth is the difference between the level of the report period
100 and the level of a fixed period. Let a_0 be the fixed period level, and the cumulative
101 growth is: $a_1 - a_0$, $a_2 - a_0 \dots$, $a_n - a_0$.

102 2. Development growth rate

103 The growth rate is a relative index which reveals the growth degree of a
104 phenomenon. It is the ratio of the growth rate to the development level of the base
105 period. The growth rate is divided into the link-relative growth rate and the fixed base
106 growth rate according to different base periods.

107 Link-relative growth rate = period-by-period growth / the development level of the
108 previous period.

109 Fixed based growth rate = cumulative growth / the development level of the fixed
110 period

111 Fifthly, the ARIMA model in the time series was used for predictions.

Results

Analysis on the overall height trend

Table 1. One-way analysis of variance and trend test of Han students' height from 1985 to 2014

	Boys				Girls			
	Variance analysis		Trend test		Variance analysis		Trend test	
Index	F-value	P-value	F-value	P-value	F-value	P-value	F-value	P-value

Fig 1. The development trend of the mean height of Han students in the full-range school age group from 1985 to 2014

During the 29 years, the height of Chinese Han students aged 7-18 continued to grow (Fig 1), but the difference in the overall mean change of the full-range school age group was not significant (Table 1).

Analysis on the secular height trend

From 1985 to 2014, the mean height of the Han boys aged 7-18 in the same age group showed an upward trend as times went on (the difference is statistically significant, as shown in Table 2 and Table 3). The time series analysis was used to make a dynamic analysis on the cumulative growth of the height indexes. The mean heights of boys aged 7 -18 increased by 3.99cm, 8.01 cm, 8.31 cm, 8.63 cm, 9.81 cm, 11.62 cm, 10.38 cm, 9.22 cm, 7.50 cm, 5.59 cm, 4.51 cm and 3.79 cm, respectively. Boys aged 12 had the largest growth (11.62 cm). The mean height of boys in the full-range school age group increased by 7.61cm. The link-relative growth of boys in the full-range school age group was respectively 2.64 cm, 0.65 cm, 0.96 cm, 1.13 cm, 1.26cm, and 1.23cm in the seven tests. According to an analysis on the period-by-period growth, boys had the largest growth from 1985 to 1991. And the height growth of boys aged 7 to 9 in 1991 was respectively 2.32 cm, 2.44 cm, and 2.41 cm, and the corresponding figure of boys aged 12, 13 and 14 was 4.17 cm, 4.32 cm, and 2.62 cm, respectively.

Table 2. Statistics for the comparison between the link-relative growth rate of the mean height (unit: cm) of boys and girls

Gender	1985	1991	1995	2000	2005	2010	2014
Male	-	1.84	0.44	0.65	0.78	0.86	0.82
Female	-	1.47	0.36	0.48	0.55	0.66	0.73
Difference value	-	0.37	0.08	0.17	0.24	0.20	0.10

In 1984, Tanner called the phenomenon that the Japanese children and adolescents had a height growth rate of over 2.5 cm per 10 years in the period from 1960 to the mid-1980s the “a miracle in the history of human biology” 3. Except Han boys aged 7, 17 and 18, the boys of the other age groups had a height growth rate greater than 2.5 cm per 10 years, from 1985 to 1995, and the mean height growth of the full-range school age group was 2.09 cm (Table 4). In this period, the height growth of the Han boys aged 12 was 5.30 cm and that of the boys aged 13 was 5.24 cm. And the mean height growth of the primary and middle school age group was 3.29 cm. From 2005 to 2014, the height growth of the boys aged 9 to 14 was also

greater than 2.5 cm/10 years, and mean height growth of the full-range school age group was 2.49 cm (Table 4). According to an analysis on the mean growth change in the third decade, the mean height growth had a downward trend in the second decade, but the mean height growth increased and did not show a slowdown trend. In the 29 years from 1985 to 2014, the Han boys aged 7-18 increased by 7.61 cm in their average height (Table 4). As can be seen from an analysis on the link-relative growth rate of the mean height of the Han boys, the average growth rate of the boys aged 12 was highest (1.32%) in the 29 years, and that of the boys aged 11 was the second highest (1.15%) (Table 4). The link-relative height growth of the full-range school age group were 2.64 cm, 0.65 cm, 0.96 cm, 0.13 cm, 1.26 cm and 1.23 cm, respectively, in different periods from 1985 to 2014.

In the 29 years from 1985 to 2014, the mean height of the Han girls aged 7-18 in the same age group had a significant growth as times went on (Table 5). The time series analysis was used to make a dynamic analysis on the cumulative growth of the height indexes. In the seven times tests of the girls in the same age group, the girls aged 11 had the largest cumulative growth (9.6 cm); the girls aged 10 had a cumulative growth of 8.84 cm; the girls aged 7 had a cumulative growth of 6.66 cm and a mean height of 125.12 cm; the girls aged 18 had a cumulative growth of 3.32 cm and a mean height of 159.40 cm (Table 5). According to an analysis on the period-to-period growth of the girls, the height growth from 1985 to 1991 is the largest; and the girls aged 9, 10, 11 and 12 had the largest growth (2.57 cm, 2.80 cm and 3.29 cm and 4.62 cm, respectively) (Table 5). According to an analysis on the mean height growth of the full-range school age group in different periods, the mean growths in the seven tests were 2.03 cm, 0.51 cm, 0.69 cm, 0.96 cm, 0.94 cm, and 1.06 cm, respectively (Table 5). This indicates that the height growth of girls

decreased slightly from 1991 to 1995, but the height of the Han girls had been increasing steadily from 1995 to 2014.

In the periods from 1985 to 1995, 1995 to 2005, and 2005 to 2014, the mean height growth was 2.57 cm, 1.45 cm, and 2.00 cm, respectively (the difference was statistically significant, $P < .001^{**}$) (Table 6). In the first decade, the “growth miracle” appeared on girls aged 7 to 13. The “growth miracle” did not appear in the second decade. And in the third decade, the girls aged 9 to 12 had a high growth rate. Their growth were 2.5 cm, 2.83 cm, 3.26 cm and 2.91 cm, respectively. From 1985 to 2014, the mean heights of boys aged 7 -18 increased by 6.66 cm, 7.36 cm, 8.00 cm, 8.84 cm, 9.60 cm, 8.66 cm, 5.57 cm, 4.65 cm, 3.95 cm, 3.32 cm, 2.87 cm and 3.32 cm, respectively. Girls aged 11 had the largest growth (9.60 cm). The mean height of girls in the full-range school age group increased by 6.07 cm. The link-relative growth of girls in the full-range school age group was respectively 2.03 cm, 0.51 cm, 0.69 cm, 0.76 cm, 0.94 cm, and 1.06 cm in seven tests. According to an analysis on the period-by-period growth, in the 29 years from 1985 to 2014, girls aged 11 showed the highest average growth rate (1.12%), followed by girls aged 10 and 9, with an average growth rate of 1.07% and 1.01%. The average link-relative growth rate decreased in 1995, while the corresponding figure in the other periods increased as times went on. From 2000 to 2014, the average growth rate was 0.48%, 0.55%, 0.66% and 0.73%, respectively.

204 Urban-rural and sex difference in height development

205 Urban-rural differences in height development

206 According to a comparison between the height of urban and rural boys,
207 the mean height of urban boys aged 7-18 was 4.18 cm greater than that of
208 rural boys in 1985(Table 7). And the urban-rural differences in the mean height
209 of boys were 3.58 cm, 3.18 cm and 2.41 cm, respectively in 1995, 2005 and
210 2014. It can be seen that the urban-rural difference in the mean height of boys
211 had been gradually narrowed.

212 According to a comparison between the height of urban and rural girls
213 (Table 8), the mean height of urban girls aged 7-18 was greater than that of
214 rural boys, and the urban-rural difference in the mean height of girls had been
215 gradually bridged. The results of comparisons showed that the urban-rural
216 differences in the mean height of girls were 3.68 cm, 3.12 cm, 2.62 cm, and
217 1.98 cm, respectively in 1985, 1995, 2005 and 2014.

222 Sex differences in height development

223 Overall, the sex difference in the mean height of boys and girls aged 7 to
 224 18 had been widened constantly in the period from 1985 to 2014. And the sex
 225 differences in 1985, 1995, 2005, and 2014 were 3.27 cm, 4.03 cm, 4.64 cm,
 226 and 5.13 cm, respectively (Table 9). According to a comparison between the
 227 link-relative height growth rate of boys and girls, the one of boys was higher
 228 than that of girls. The sex difference in the height growth rate was the largest in
 229 1991, and the difference was 0.37%. The sex difference in the link-relative
 230 growth rate was gradually narrowed from 2005 to 2010 and 2014, and such
 231 difference was 0.24%, 0.20% and 0.10%, respectively. According to a
 232 comparative analysis on the specific age difference in the height development,
 233 girls had the largest height growth at the age of 11, with a mean cumulative
 234 growth of 9.60 cm, while boys had the largest height growth at the age of 12,
 235 with a mean cumulative growth of 11.62 cm (Table10).

236 The research found that the sex difference in the mean height of boys and
 237 girls aged 7-18 in the period from 1985 to 2014 increased constantly, and the
 238 difference value was 3.27 cm, 4.03 cm, 4.64 cm, and 5.13 cm, respectively in
 239 1985, 1995, 2005 and 2014. That is to say, the sex difference in height
 240 development had been constantly widened. This may be because growth
 241 potentials of boys and girls are different. Compared with girls, boys are more

sensitive to the good living environment in their physical development, but more vulnerable to malnutrition, diseases and adverse social factors. Therefore, the sex difference in height can be used as a biological index for measuring whether the living environment is good. The height growth trend of Han boys aged 7-18 is more distinct than that of girls, perhaps because the living environment in China has been constantly improved.

Height prediction

The ARIMA model was used to predict the height mean and 95% confidence interval of Han boys and girls aged 7-18 in 2024. A statistical test was made on the selected model parameter estimates. The P-values of the 7-year-old and 18-year-old models were 0.004 and 0.01, respectively, and the P-values of the other age groups were $P < .001$. Model residuals were tested by white noise ($P > 0.05$). The 12-year-old girl model was ARIMA (1,1,1); the AR coefficient test $P < .001$; and MA coefficient test $P = 0.003$. The P-values of other models were less than 0.001, and the residual sequence was tested by white noise.

In 2024, the mean height of boys and girls in each age group from 7 to 18

will continue to grow. In 2024, boys are expected to have the largest height growth (3.57 cm) at the age of 12, and have the second largest height growth (3.29 cm) at the age of 11. Boys are expected to have a 0.86 cm height growth at the age of 18. Girls are expected to have the largest height growth (3.5 cm) at the age of 11, and have the second largest height growth (2.44 cm) at the

274 Discussion

275 The Secular Growth Trend is one of the major phenomena in human
276 biology in the last two centuries. It has the following manifestations: Children's
277 growth level has been improved; pubertal development has been completed at
278 an earlier time; the adult height has increased constantly [11]. In the existing
279 research, Ji Chengye et al. analyzed the secular growth trend of children and
280 adolescents in large cities in China in the period from 1979 to 2005, and found
281 that children and adolescents had the fastest height growth from 1985 to 1995
282 (the first decade in this study). Meanwhile, the study of Liao Wenke [12] also
283 showed that the height growth of all types of students from 1985 to 1995 was
284 greater than that in the period from 1995 to 2005. This research further
285 calculated the overall trend of height development of Chinese Han students in
286 the third decade. The cumulative growth (2.49 cm) of boy students in the third
287 decade (2005-2014) was higher than that (2.09 cm) in the second decade and
288 lower than that (3.29 cm) in the first decade. Girls showed the same trend of
289 height development. This indicates that Chinese Han students aged 7 to 18
290 were still in a stage of height development at a high "positive" accelerated
291 growth rate.

292 From 1985 to 2014, the mean height of the Han boys aged 7-18 in the
293 same age group had increased constantly as times went on. In the 7 tests, the
294 link-relative height, growth of boys in the full-range school age group were 2.64
295 cm, 0.65 cm, 0.96 cm, 0.13 cm, 1.26 cm and 1.23 cm, respectively in different
296 periods, and the corresponding figure of girls were 2.03 cm, 0.51 cm, 0.69 cm,
297 0.96 cm, 0.94 cm and 1.06 cm. This indicates that the height growth of

298 students was the largest in the period from 1991 to 1995, perhaps for the
 299 following reasons. Firstly, it is related to China's implementation of reform and
 300 opening up in the early 1980s. In 1985, China's per capita GDP was 855 yuan,
 301 and increased to 4, 854 yuan in 1995. The per capita food expenditure of
 302 urban areas increased from 352 yuan to 1,766 yuan, and that of rural areas
 303 increased from 183 yuan to 768 yuan. Owing to the improvement of the
 304 nutritional status and the effective prevention and control of common diseases
 305 affecting the health of children and adolescents, the growth and development
 306 of children and adolescents had been accelerated for a long time, and the
 307 height of children had increased greatly in this period. Secondly, it is also
 308 attributed to the rapid development of school sports. At this stage, the national
 309 sports facilities of China had an educational orientation. National policies of
 310 China gave much attention to the requirements of sports development for
 311 sports facilities, kept a watchful eye on students' constitution and health, and
 312 fulfilled the requirements of sports qualification standards for sports facilities
 313 [13]. In 1982, China began to implement the "National Physical Training
 314 Standard". This standard broke the old pattern that sports functional
 315 departments were in full charge of school sports, created a management
 316 model with the participation of various school parties, changed the old
 317 evaluation criteria that measured the sports accomplishment solely by their
 318 sports skills, and builds a multi-objective and multi-directional evaluation
 319 system for measuring the sports accomplishment of students. According to
 320 statistics, from 1979 to 1982, the number of people who passed the "National
 321 Physical Training Standard" in China was eight times that of 1978. In 1990,
 322 Beijing hosted the Asian Games for the first time. The government invested

more efforts into the propaganda of sports and improved the sports infrastructure. The enthusiasm of Chinese people for sports had run unprecedentedly high, and the high attention to sports also affected the height development of students. Thirdly, in their growth and development, children and adolescents not only had a secular growth trend, but also overcame the developmental delays caused by the early adverse factors and speeded up to return to the original track of secular growth [14].

According to this research, the sex difference in the mean height of boys and girls aged 7-18 in the period from 1985 to 2014 had increased constantly, and the difference value was 3.27 cm, 4.03 cm, 4.64 cm, and 5.13 cm, respectively in 1985, 1995, 2005 and 2014. That is to say, the sex difference in height development had been constantly widened. This may be because growth potentials of boys and girls are different. Compared with girls, boys are more sensitive to the good living environment in their physical development, but more vulnerable to malnutrition, diseases and adverse social factors. Therefore, the sex difference in height can be used as a biological index for measuring whether the living environment is good or not [10]. The height growth trend of Han boy students aged 7-18 is more distinct than that of girls, perhaps because the living environment in China has been constantly improved.

According to a comparison between the height of urban and rural boys, the mean height of urban boys aged 7-18 was 4.18 cm greater than that of rural boys aged 7-18 in 1985. And the urban-rural differences in the mean height of boys were 3.58 cm, 3.18 cm and 2.41 cm, respectively in 1995, 2005 and 2014. And the urban-rural differences in the mean height of girls were 3.68

348 cm, 3.12 cm, 2.62 cm, and 1.98 cm, respectively in 1985, 1995, 2005 and 2014.
349 Thus it can be seen that the urban-rural difference in the mean height of
350 primary and middle school students had been gradually bridged. This may be
351 related to reasons for the continuous positive changes in China's living
352 environment [15].

353 In 2024, the mean height of boys and girls in each age group from 7 to 18
354 will continue to grow. In 2024, boys are expected to have the largest height
355 growth (3.57 cm) at the age of 12, while girls are expected to have the largest
356 height growth (3.5 cm) at the age of 11.

357 **Conclusions**

358 From 1985 to 2014, the mean height of Han students in the same age
359 group from 7 to 18 had increased constantly as times went by. In the period
360 from 1985 to 1991, the height growth of boys/girls was the largest ; Sex
361 differences in height development was observed and the gender differences
362 had been widened ; We also observed the Urban-rural differences in height
363 development. The mean height of urban students was greater than that of rural
364 students, but their height difference had been narrowed gradually ; In 2024, the
365 mean height of boys and girls aged 7-18 are predicted to grow continuously.
