SUMMARY

The World Health Organization has declared SARS-CoV-2 virus outbreak a world-wide pandemic. Individuals infected by the virus exhibited different degrees of symptoms, the basis of which remains largely unclear. Currently, though convalescent individuals have been shown with both cellular and humoral immune responses, there is very limited understanding on the immune responses, especially adaptive immune responses, in patients with severe COVID-19. Here, we examined 10 blood samples from COVID-19 patients with acute respiratory distress syndrome (ARDS). The majority of them (70%) mounted SARS-CoV-2-specific humoral immunity with production of neutralizing antibodies. However, compared to healthy controls, the percentages and absolute numbers of both NK cells and CD8⁺ T cells were significantly reduced, accompanied with decreased IFN γ expression in CD4⁺ T cells in peripheral blood from severe patients. Most notably, we failed in detecting SARS-CoV-2-specific IFN γ production by peripheral blood lymphocytes from these patients. Our work thus indicates that COVID-19 patients with severe symptoms are associated with defective cellular immunity, which not only provides insights on understanding the pathogenesis of COVID-19, but also has implications in developing an effective vaccine to SARS-CoV-2.

Keywords: SARS-CoV-2, acute respiratory distress syndrome, adaptive immunity, neutralization antibody, T cells

1 Introduction

2 Identified in December, 2019, coronavirus disease 2019 (COVID-19) caused by
 3 severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) (Wang et al., 2020a)
 4 has become a global public health threat. As of July 17th, 2020, 13,378,853 global
 5 cases were confirmed, of which 580,045 patients died
 6 ([https://www.who.int/emergencies/diseases/novel-coronavirus-2019/situation-](https://www.who.int/emergencies/diseases/novel-coronavirus-2019/situation-reports)
 7 [reports](https://www.who.int/emergencies/diseases/novel-coronavirus-2019/situation-reports)). The high infection rate and rapid spread make it a world-wide emergency
 8 (Di Pierro et al., 2020). However, up to date, there is no specific anti-viral medicine
 9 or vaccine available to prevent or treat COVID-19 and the current standard care
 10 relies on supportive treatments.

11 Approximately 80% of COVID-19 cases are asymptomatic or manifest mild
 12 symptoms resembling simple upper respiration tract infection. The remaining
 13 COVID-19 patients show severe or critical symptoms with severe pneumonia and
 14 acute respiratory distress syndrome (ARDS) (Gruszecka and Filip, 2020). How the
 15 immune system modifies and controls the infection is still not well understood, which
 16 may underscore the different degrees of symptoms amongst the population. Several
 17 papers were reported on the adaptive immune responses in the recovered mild
 18 COVID-19 patients. We detected SARS-CoV-2-specific antibodies and T cells in
 19 convalescent individuals (Ni et al., 2020). Grofoni et al also found that ~70% and 100%
 20 of COVID-19 convalescent subjects with mild and severe symptoms developed
 21 SARS-CoV-2-specific CD8⁺ and CD4⁺ T cells, respectively (Grifoni et al., 2020).
 22 However, there is very limited understanding on immune responses in severe
 23 COVID-19 patients during hospitalization. In a retrospective study, Chen et al
 24 observed that absolute numbers of T lymphocytes, both CD4⁺ and CD8⁺, were
 25 markedly lower in severe patients than those in moderate cases (Chen et al., 2020).

1 In contrast to the aforementioned study, Zheng et al did not observe reduced
2 lymphocytes in the severe disease group, but T cells showed elevated exhaustion
3 levels and reduced functional heterogeneity (Zheng et al., 2020). Using megapools
4 of overlapping or prediction-based peptides covering the SARS-CoV-2 proteome,
5 Weiskopf et al found CD4⁺ and CD8⁺ T cells showed activation marker expression in
6 10 out of 10 and 8 out of 10 patients with severe COVID-19 during hospitalization,
7 respectively (Weiskopf et al., 2020). For humoral responses, Lynch et al found that
8 antibody responses were higher in patients with severe than mild disease (Lynch et
9 al., 2020). And high levels of neutralizing antibodies was induced 10 days post onset
10 in both mild and severe patient, which were higher in severe group (Wang et al.,
11 2020b).

12 In order to understand immune responses and the mechanism underlying the
13 pathogenesis of severe COVID-19, we collected blood samples from 10 patients with
14 ARDS, analyzed their cellular and humoral responses specific to SARS-CoV-2, and
15 compared severe and convalescent patients. Our data reveal defective cellular
16 immunity associated with severe COVID-19. This study provides new insights on the
17 precise treatment of COVID-19 patients and evaluation of candidate vaccines.

18

19

1 Results

2 Detection of SARS-CoV-2-specific antibodies in severe COVID-19 subjects

3 To understand the immune responses to SARS-CoV-2 in severe patients, we
 4 studied 10 patients with acute respiratory distress syndrome (ARDS). Their clinical
 5 and pathological characteristics are shown in Table 1. All the patients were
 6 hospitalized at Beijing Ditan Hospital and showed severe symptoms via CT scan and
 7 were positive in SARS-CoV-2 nucleic acid testing. The mean age was 57.5 years
 8 and half of them were female. Among them, 8 (80%) showed lymphopenia. As of
 9 today, 1 patient (Pt#9) passed away and the remaining ones had recovered and
 10 were discharged from hospital. The blood samples were obtained within 20 days
 11 post symptom onset and the detail sampling day for each patient was also shown in
 12 Table 1. Human AB serum collected from healthy male AB donors in the US
 13 (GemCell, CA) was used as a negative control. Additionally, sera from nine healthy
 14 donors were obtained before the SARS-CoV-2 outbreak (HD#1-9). 5 additional
 15 healthy donors (HD#10-14) without SARS-CoV-2 infection were analyzed in our T
 16 cell assays.

17 Using sera from patients and healthy donors, IgG and IgM specific to SARS-
 18 CoV-2 NP and S-RBD antigens were analyzed using ELISA assay previously
 19 reported (Ni et al., 2020). The individual serum samples were performed by serial
 20 dilutions to calculate the area under the curve (AUC) values (Figure 1A). Compared
 21 with healthy donors, patients with severe COVID-19 showed significantly elevated
 22 anti-NP IgG AUC values (Figure 1B). The AUC values of anti-S-RBD IgG in severe
 23 cases were also significantly increased compared to those in healthy controls.
 24 Serum NP- and S-RBD-specific IgM antibodies showed significantly higher AUC
 25 values in severe COVID-19 patients than in healthy controls (Figure 1B). Notably,

1 patients #1, 4 and 7 did not develop NP- and S-RBD -specific antibody responses,
2 including IgM and IgG. As shown in Figure 1C, anti-NP and S-RBD IgG in severe
3 patients was mainly IgG1 isotype, as in convalescent individuals (Ni et al., 2020). We
4 did not detect IgG2 to either NP or S-RBD proteins (data not shown).

5 In order to understand the pathogenic mechanisms in severe patients, we
6 compared the levels of virus-specific IgG or IgM in these patients with those in
7 convalescent individuals. Serum from one convalescent COVID-19 patient was used
8 as a positive control standard to calculate the antibody titers (relative units) for all
9 samples using non-linear regression interpolations (Grifoni et al., 2020). Of note, we
10 observed no significant differences in anti-NP/S-RBD IgG or IgM between these two
11 groups (Figure 1D).

12 Taken together, these findings indicate that most severe COVID-19 patients
13 mounted IgG and IgM responses specific to SARS-CoV-2 proteins, NP and S-RBD.
14 However, the levels of humoral immune responses varied among the patients.

15

16 **Measurement of neutralizing antibody production in severe COVID-19 subjects**

17 To determine the neutralization capacity in sera from patients with severe
18 COVID-19, we performed pseudovirus particle-based neutralization assay as
19 previously described (Ni et al., 2020). As shown in Figure 2A and 2B, patients #1, 4
20 and 7, did not produce neutralizing antibodies, while patient #3 had a high
21 neutralizing antibody titer (NAT50>1000). Most severe patients (70%) had protective
22 humoral immunity to SARS-CoV-2. Notably, sera from severe patients did not show
23 significantly reduced NAT50 values than convalescent sera (Figure 2C). About 30%
24 of severe patients and 8% of convalescent individuals did not produce neutralizing
25 antibodies, respectively (Figure 2D). Around 40%, 20% and 10% of severe patients

1 showed low (NAT50: 30-500), medium (NAT50: 500-1000) and high (NAT50: >1000)
2 NAT50, respectively, while 50%, 21% and 21% in the convalescent group did.

3 Nonetheless, our results indicate that most severe patients had serum
4 neutralizing antibodies to SARS-CoV-2 infection.

5

6 **Lymphocyte numbers and function in severe COVID-19 subjects**

7 To analyze cellular immune responses to SARS-CoV-2, peripheral blood
8 mononuclear cells (PBMCs) from 10 patients with severe COVID-19 and 5 healthy
9 donors were phenotypically analyzed by flow cytometry (Figure 3A). We did not
10 detect live PBMCs in 3 out of 10 patients (Pts# 3, 4 and 5), possibly due to technical
11 issues during cryopreservation. Compared to healthy donors, there was a significant
12 decrease in the percentages of NK cells in the severe patients, but similar
13 frequencies of NKT cells (Figure 3B). Although there was a trend towards increased
14 frequencies of T cells (CD3⁺CD56⁻) in the patient blood, the absolute numbers of T
15 cells were significantly decreased compared to those in blood from healthy controls
16 (Figure 3C). Notably, the percentages and absolute numbers of CD8⁺ T cells were
17 reduced dramatically, while the frequency of CD4⁺ T cells was elevated compared
18 with those in healthy donors. As a result, the CD4:CD8 ratios were significantly
19 higher in severe patients than in the healthy donors (6.7 ± 1.3 in COVID-19 vs $2.5 \pm$
20 0.3 in HD, $P=0.0226$) (Figure 3B). Thus, the severe patients exhibited reduced
21 cytotoxic lymphocytes, both NK and CD8⁺ T cells.

22 To further assess the function of the T cells in the severe patients, we stimulated
23 T cells with phorbol myristate acetate (PMA) and ionomycin and then measured
24 cytokine production. As shown in Figure 4A and 4B, CD4⁺ T cells from severe
25 patients expressed significantly lower levels of IFN γ than those from healthy donors.

1 We observed no apparent difference in the frequencies of $\text{TNF}\alpha$ -expressing CD4^+ T
2 cells, but significantly reduced percentages of $\text{IFN}\gamma^+ \text{TNF}\alpha^+$ T cells (Figure 4C and
3 4D), consistent with a published report (Chen et al., 2020). Only 2 out of 7 patients
4 had detectable $\text{IL-17A}^+ \text{CD4}^+$ T cells, which expressed $\text{TNF}\alpha$, but not $\text{IFN}\gamma$ (Figure
5 4D).

6 Despite the decreased frequencies of CD8^+ T cells in PBMCs from the patients,
7 these CD8^+ T cells expressed similar levels of cytokines $\text{IFN}\gamma$ and $\text{TNF}\alpha$ as the ones
8 from healthy donors (Figure 4E and 4F). In addition, similar frequencies of
9 $\text{IFN}\gamma^+ \text{TNF}\alpha^+ \text{CD8}^+$ T cells were found in severe patients and healthy donors (Figure
10 4G).

11 We also evaluated capacities of cytokine production in CD3^+ cells, likely NK cells.
12 As shown in Figure 4H, these cells in severe patients expressed significantly
13 reduced levels of $\text{IFN}\gamma$ and $\text{TNF}\alpha$ than those in healthy donors. We did not observe
14 significant difference in terms of the frequency of $\text{IFN}\gamma^+ \text{TNF}\alpha^+$ cells between these
15 two groups (Figure 4H).

16

17 **Cellular immune responses to SARS-CoV-2 in severe COVID-19 subjects**

18 To further measure virus-specific cellular immunity, we treated PBMCs with
19 recombinant NP, S-RBD and S proteins, followed by $\text{IFN}\gamma$ ELISpot analysis. As
20 shown in Figure 5A, the absolute numbers of T cells produced $\text{IFN}\gamma$ in response to
21 anti-CD3 were decreased dramatically in PBMCs from severe patients than those
22 from healthy donors. More strikingly, we did not detect any SARS-CoV-2-specific T
23 cells in all the tested severe patients, whereas one out of ten T cells could secret
24 $\text{IFN}\gamma$ after exposure to NP protein in convalescent individuals (Figure 5B).

1 Thus, T cells in the severe COVID-19 patients failed in developing cellular
2 immunity to SARS-CoV-2.

3

4

1 Discussion

2 In this study, we characterized humoral and cellular immunity in severe COVID-
3 19 patients during hospitalization. Although most patients developed anti-SARS-
4 CoV-2 IgG and IgM responses, humoral immune responses varied widely among the
5 patients. The percentages and absolute numbers of both NK cells and CD8⁺ T cells
6 were significantly reduced, accompanied with decreased Th1 cell response in
7 peripheral blood from severe patients. Most notably, we failed in SARS-CoV-2-
8 specific IFN γ production in these patients.

9 In this study, most severe patients had reduced Th1 cell responses, consistent
10 with the published report (Chen et al., 2020). Another report showed that peripheral
11 blood of a severe COVID-19 patient had a strikingly high number of CCR6⁺ Th17
12 cells (Xu et al., 2020). In addition, several papers proposed use of therapies directed
13 at Th17 cells and IL-17A signaling in treating COVID-19 patients (De Biasi et al.,
14 2020; Orlov et al., 2020; Wu and Yang, 2020). However, we observed no significant
15 Th17 cell responses in most of the severe patients (5/7) with only one patient
16 showing elevated IL-17A expression. Several possibilities may account for the
17 discrepancy. One is different markers used for defining Th17 cells. The above-
18 mentioned paper used CCR6 on CD4⁺ T cells to define Th17 cells, whereas we used
19 IL-17A expression in CD4⁺ T cells. Another is different patient cohort and disease
20 severity. Sample timing during disease course is another possibility, since T cell
21 responses are dynamic. Given not all the severe COVID-19 patients had increased
22 IL-17A expression, one may not want to treat all patients with IL-17A inhibitors.

23 5 healthy donors (HD#10-14) with a mean age of 29.4 years were included in our
24 T cell assays, which are not age-matched with severe patients with a mean age of
25 57 years. Compared to healthy controls, severe patients showed reduced

1 percentages of CD8⁺ T cells and IFN γ -expressing CD4⁺ T cells. Previously, Carr et al
2 found that frequencies of Th1 and CD8⁺ T cells were enhanced with age (Carr et al.,
3 2016). Thus, the differences we observed between healthy controls and severe
4 patients were unlikely caused by age.

5 In our study, antigens-specific IFN γ expression was not detected in severe
6 patients, in contrast to the report (Weiskopf et al., 2020). We used antigen-mediated
7 IFN γ ELISpot analysis to detect antigen-specific T cells, while the other group used T
8 cell receptor-dependent activation marker assay in measuring the expression of
9 CD137 and CD69. Since AIM assay did not measure effector function by T cells, it is
10 possible that virus-specific T cells are “exhausted”. Different patient cohort and
11 sample timing may account for the different results.

12 In summary, we detected anti-SARS-CoV-2 antibody responses in most severe
13 cases, while impaired cellular responses were observed in all severe COVID-19
14 patients. Our results thus provide insight in the pathogenesis of severe COVID-19.
15 They suggest that induction of cellular immunity is vital in controlling SARS-CoV-2
16 infection, which also has implications in development of an effective vaccine.

2 **RESOURCE AVAILABILITY**

3 ***Lead Contact***

4 Further information and requests for resources and reagents should be directed to
5 and will be fulfilled by the lead contact, Chen Dong (chendong@tsinghua.edu.cn)

6 ***Materials Availability***

7 The plasmids (pET28-N-6XHis and pEF1a-S-RBD-6His) generated in this study will
8 be made available on request from the Lead Contact without restriction.

9 ***Data and Code Availability***

10 The study did not generate any unique dataset or code.

11

12 **EXPERIMENTAL MODEL AND SUBJECT DETAILS**

13 **COVID-19 patient blood samples**

14 The blood samples of severe COVID-19 patients defined as severe lower
15 respiratory tract infection or pneumonia with fever plus any one of the following:
16 tachypnea, respiratory distress, or oxygen saturation less than 93% on room air
17 according to the guidelines released by the national Health Commission of China
18 were obtained from Ditan hospital in Beijing. All procedures followed were in
19 accordance with the ethical standards of the responsible committee on human
20 experimentation (the institutional review board at Tsinghua University and at Ditan
21 hospital) and with the Helsinki Declaration of 1975, as revised in 2000. All studies
22 were approved by the Medical Ethical Committee at Tsinghua University. Informed
23 consent was obtained from all subjects for being included in the study. All patient

1 data were anonymized before study inclusion. See Table 1 for full patient information,
2 including age, sex, and health status.

3

4 Cell Lines

5 HuH-7 cells originally taken from a liver tumor in a Japanese male were cultured in
6 DMEM supplemented with 10% FBS. Cells were grown at 37 °C in a 5% CO₂ setting.

7

8 **METHOD DETAILS**

9 **Expression and Purification of recombinant proteins**

10 The recombinant His-tagged NP of SARS-CoV-2 was expressed in E. coli by a T7
11 expression system, with 1 mM IPTG induction at 37 °C for 4 h. The recombinant His-
12 tagged S-RBD (amino acids 319-541) was expressed by a mammalian system in
13 293F cells. Purified proteins were identified by SDS-PAGE gels and stained with
14 Coomassie blue.

15

16 **Isolation of PBMC**

17 PBMCs were isolated from anti-coagulant blood using Ficoll-Hypaque gradients (GE
18 Healthcare Life Sciences, Philadelphia, PA) as previously described (Xie et al., 2018)
19 under the biosafety level 3 facility in AMMS. To isolate PBMCs, blood diluted with
20 PBS, was gently layered over an equal volume of Ficoll in a Falcon tube and
21 centrifuged for 30-40 minutes at 400-500 g without brake. Four layers formed, each
22 containing different cell types. The second layer contained PBMCs. These cells
23 could be gently removed using a Pasteur pipette and added to warm medium or PBS
24 to wash off any remaining platelets. The pelleted cells were then counted and the

percentage viability was estimated using Trypan blue staining. Cells were then cryopreserved for future study.

Anti-SARS-CoV-2 IgG/IgM ELISA

For IgM/IgG testing, 96-well ELISA plates were coated overnight with recombinant NP and S-RBD (100 ng/well). The sera from COVID-19 patients were incubated for 1 h at 37°C. An anti-Human IgG-biotin conjugated monoclonal antibody (Cat. SSA009, Sino Biological Inc., Wayne, PA) and streptavidin-HRP were used at a dilution of 1:5000 and 1:250, respectively, and anti-human IgM-HRP conjugated monoclonal antibody (Cat. bs-0345G-HRP, Biosynthesis Biotechnology Inc. Beijing, China) was used. The OD value at 450 nm was calculated. The area under the curve (AUC) was calculated by Prism 8 (Graphpad). As a second analytical approach (Grifoni et al., 2020), the serum from one convalescent mild COVID-19 patient was used as a positive control standard. In order to quantify the amount of anti-NP/S-RBD IgG or anti-NP/S-RBD IgM present in each specimen, the positive control standard was run on each plate to calculate antibody titers (relative units) for all samples using non-linear regression interpolations.

Anti-SARS-CoV-2 IgG1/IgG3 ELISA

For IgG1/IgG2/IgG3 test, 96 well ELISA plates were coated (80 ng/well) overnight with recombinant NP and S-RBD. Plates were washed and the sera from COVID-19 patients were incubated for 1 h at 37°C. After washing, an anti-Human IgG1-HRP conjugated monoclonal antibody (Cat. C030248, BaiaoTong Experiment Center, LY), and an anti-human IgG3-HRP conjugated monoclonal antibody (Cat.C030246, BaiaoTong Experiment Center, LY), all validated by the company for their specificity,

1 were used at a dilution of 1:4000 for 1 h at RT. After washing, TMB substrate
2 solution was added. The OD value at 450 nm was calculated. The area under the
3 curve (AUC) was calculated by Prism 8 (Graphpad).

4

5 **Neutralizing antibody assay**

6 Pseudovirus expressing the SARS-CoV-2 S protein was produced. pNL43Luci and
7 GP-pCAGGS were co-transfected into 293T cells. 48 hours later, SARS-CoV-2
8 pseudovirus-containing supernatants were mixed with at least 6 serially diluted
9 serum samples from the COVID-19 patients at 37°C for 1 hour. Then the mixtures
10 were transferred to 96-well plates containing monolayers of Huh-7 cells (Nie et al.,
11 2020). 3 hours later, the medium was replaced. After incubation for 48 h, the cells
12 were washed, harvested in lysis buffer and analyzed for luciferase activity by the
13 addition of luciferase substrate. Inhibition rate = $[1 - (\text{the sample group} - \text{the cell control group}) / (\text{the virus control group} - \text{the cell control group})] \times 100\%$. The neutralizing
14 antibody titer (NAT50) were calculated by performing S-fit analysis via Graphpad
15 Prism 7 software.

16

17 **Interferon Gamma (IFN γ) ELISpot**

18 IFN- γ -secreting T cells were detected by Human IFN γ ELISpot^{pro} kits (MABTECH AB,
19 Sweden) according to the manufacture protocol. Fresh PBMCs were plated in
20 duplicate at 150k per well and then incubated 48h with 1uM of recombinant proteins.
21 Spots were then counted using an AID ELISpot Reader System (iSpot, AID GmbH).
22 The number of spots was converted into the number of spots per million cells and
23 the mean of duplicate wells plotted.

24

FACS staining

PBMCs were washed with PBS plus 2% FBS (Gibco, Grand Island, NY), and then Fc blocking reagent (Molten Bio, Inc., Auburn, CA) was added followed by a wash with PBS plus 2% FBS. Cells were then incubated for 30 min on ice with anti-CD3 (OKT3) (BioLegend), anti-CD8 (SK1) (BD), anti-CD56 (HCD56) (BioLegend) and live/dead fixable aqua dye (eF660, eBioscience), washed twice with PBS plus 2% FBS and then stored at 4 °C until acquired by FACS Verse (BD Biosciences, San Jose, CA). Data were analyzed using FlowJo software (Version 10.0.8, Tree Star Inc., Ashland, Or).

QUANTIFICATION AND STATISTICAL ANALYSIS

Prism 8 software is used for statistical analysis. Student's t test was performed for two-group analysis. Pearson's correlation coefficients were calculated. *P* values less than 0.05 were considered to be statistically significant.

Table 1 Clinical and pathological characteristics of the severe COVID-19 patients

Pt#	Sex	Age	Fever	Fatigue	ARDS	Lymphocyte Count	Days in hospital	Sampling day post onset	BT NA test	Discharge CT scan	Discharge NA test
#1	F	69	yes	no	yes	0.65X10 ⁹ /L	43	13	P	improvement	N
#2	M	55	yes	no	yes	1.24X10 ⁹ /L	27	18	P	improvement	N
#3	M	37	yes	no	yes	0.53X10 ⁹ /L	47	19	P	improvement	N
#4	M	52	yes	no	yes	0.94X10 ⁹ /L	39	8	P	improvement	N
#5	F	58	yes	no	yes	0.78X10 ⁹ /L	50	12	P	improvement	N
#6	M	40	yes	no	yes	1.13X10 ⁹ /L	51	11	P	improvement	N
#7	F	70	yes	no	yes	0.75X10 ⁹ /L	36	11	P	improvement	N
#8	F	66	yes	Yes	yes	0.69X10 ⁹ /L	43	2	P	improvement	N
