Running Title: Small EVs-TGF β induces pulmonary vascular injury

This article has an online data supplement.

ABSTRACT

Rationale: Extracellular vesicles (EVs) have emerged as important mediators in cell-cell communication and disease pathogenesis; however, their relevance in pulmonary hypertension (PH) secondary to HIV infection is yet to be explored.

Objective: To examine the role of circulating small EVs and monocyte-derived macrophage (MDM) EVs in the development of HIV-associated PH

Methods: EVs isolated from plasma of HIV-infected drug users and non-users with/without PH and from supernatants of HIV-infected MDMs treated with/without second hit of cocaine were studied for their effect on vascular dysfunction both *in vitro* and *in vivo*.

Measurements and Main Results: We report significantly higher numbers of plasma derived EVs (PEVs) carrying higher levels of TGF- β 1 in people living with HIV (PLWH) that had PH compared to non-PH PLWH. Importantly, levels of these TGF- β 1 loaded PEVs correlated with pulmonary arterial systolic pressures, CD4 counts, but not with diffusion capacity for carbon monoxide or viral load. Correspondingly, enhanced TGF- β 1-dependent pulmonary endothelial injury and smooth muscle hyperplasia was observed. Cocaine treatment of HIV-1 infected-MDMs resulted in increased number of TGF- β 1 high-EVs. Intravenous injection of these EVs in rats led to increased right ventricle systolic pressure accompanied with myocardial injury and increased levels of serum endothelin-1, TNF- α , and cardiac Troponin-I. Conversely, pretreatment of rats with TGF β -Receptor 1 inhibitor prevented these EV-mediated changes.

Conclusion: Findings define the ability of macrophage-derived small EVs to cause pulmonary vascular modeling and PH via modulation of TGF- β signaling and suggest clinical implications of circulating TGF- β high-EVs as a potential biomarker of HIV-PH.

Keywords: Monocytes, smooth muscle dysfunction, endothelial injury, pulmonary hypertension, inflammation

INTRODUCTION

Pulmonary arterial hypertension (PAH) is one of the most devastating non-infectious complications related to HIV infection and echocardiographic evidences suggest prevalence of increased pulmonary artery systolic pressure (PASP) in 2.6-15.5% of people living with HIV (PLWH) (1), (2). HIV-associated PAH falls under Group I pulmonary hypertension (PH) and the risk factors such as cocaine, methamphetamine and intravenous drug use (IVDU) in PLWH can potentiate the development of HIV-PAH (2-4). Furthermore, with the increasing burden of cardiac and chronic respiratory complications in PLWH, the prevalence of secondary PH is suggested to increase as well, in these individuals (5, 6).

The presence of interstitial and perivascular infiltration of inflammatory cells has been linked to intimal and medial thickening of blood vessels associated with PH (7, 8). Recently, we reported increased perivascular macrophages in the remodeled thickened vessels in the lung sections from HIV-infected humans, simian immunodeficiency virus (SIV)-infected macaques and HIV-transgenic (HIV-Tg) rats, particularly in the presence of illicit drug exposure (9, 10). However, the extent to which the perivascular inflammation is involved in the thickening and occlusion of blood vessels is elusive. It is believed that inflammation precedes vascular remodeling in PAH and is more often an origin rather than a result of PAH (7, 8). Circulating monocytes contribute to increased interstitial macrophages observed around the remodeling pulmonary vessels in PH (11, 12).

Other than the direct release of viral proteins, cytokines and growth factors to the vascular cells, immune cells may also deliver their molecular cargo through the release of extracellular vesicles (13, 14). Extracellular vesicles (EVs) are small membrane vesicles ranging from 30-1000 nm and are involved in intercellular communication by delivering protein/nucleic

acid cargo to surrounding cells. Studies have emphasized upon changes in the EV cargo to the development of various diseases in animal models including PAH (15, 16). However, limited studies have associated the levels of circulating membrane vesicles with pulmonary vascular resistance in PAH patients (17, 18). These studies were focused on larger micro-particles and lacked the details on type, size and composition of EVs, leaving open the question of the role of small EVs.

Recent reports suggest the presence of viral proteins in the bronchoalveolar lavage fluid - and plasma -derived EVs from PLWH (19, 20) (21). Given the importance of TGF- β signaling in the development of PH (22, 23) (24) and recent reports showing the presence of TGF- β 1 on the surface and within exosomes (25), we hypothesize that the increased levels of TGF- β -loaded EVs in the plasma from PLWH, may associate with the presence of PH and that EVs released by HIV-infected monocyte-derived macrophages to cause the pulmonary vascular changes and right ventricle dysfunction in wild-type and non-infectious HIV-Tg rats.

MATERIAL AND METHODS

Detailed description of methods and statistical analyses is provided in the online supplement.

RESULTS

Plasma-derived EVs (PEVs) are elevated in HIV infected and /or cocaine users. Number of EVs were compared in the plasma samples from HIV-infected individuals with (PLWH+Coc, n=15) or without history of cocaine abuse (PLWH, n=15) and uninfected individuals with the history of cocaine abuse (Coc, n=15) and non-drug users (UI, n=15) (Table 1). Gender, race and CD4 cell count were the only variables observed to be significantly different among groups

(Table 1). NanoSight analysis showed highest total number of EVs in the plasma from PLWH-cocaine users when compared with all other groups (Fig. 1A-B) with significant higher numbers of EVs observed in the size-range of 100-250 nm (Fig. 1C). These small EVs were further characterized by TEM demonstrating classic lipid bi-layered structures (Fig. 1D) and by western blot showing the presence of exosomal markers (Fig. 1E).

PEVs from HIV-infected and/or cocaine users promote TGF- β dependent pulmonary endothelial and smooth muscle dysfunction. EVs are readily taken up by human pulmonary arterial smooth muscle cells (HPASMCs) (21) as well as by human pulmonary microvascular endothelial cells (HPMECs) (Supplementary Figure IIA). Addition of PLWH+Coc or Coc group PEVs on HPMECs for 24h resulted in significant increased apoptosis when compared to the treatment with an equal amount of EVs from UI controls (Fig. 2A). Alternatively, significant increased proliferation of HPMECs and HPASMCs was observed in response to 48h treatment with PEVs from PLWH+Coc, PLWH or Coc when compared with the cells loaded with UI PEVs (Fig. 2B & C). This increased proliferation of both cell-types on treatment with PLWH+Coc EVs was higher when compared to PLWH EVs, although not significant. Nevertheless, a significantly higher number of EVs observed in the plasma of PLWH+Coc group ($10.9 \times 10^6 \pm 3.2/0.5\text{ml}$) compared to PLWH-group plasma ($5.3 \times 10^6 \pm 2.8/0.5\text{ml}$) (Fig. 1B) is expected to have more cumulative effect on the cellular injury *in-vivo*.

Analysis of TGF- β 1 levels in PEVs showed significant increased levels of active (Fig. 2D) as well as total (active plus latent) (Fig. 2E). TGF- β 1 in PEVs from HIV-uninfected cocaine user (Coc) and PLWH+Coc groups when compared to PEVs from UI controls. Interestingly, levels of TGF- β 1 in PLWH-PEVs were same as observed in UI-PEVs (Fig. 2D-E) and higher levels in

PEVs from PLWH+Coc group were also significant compared to PLWH group. Treatment of cells in the presence of TGF β -Receptor 1 inhibitor: SB431542 (10 μ M) could significantly rescue the PLWH+Coc PEV-mediated enhanced endothelial as well as smooth muscle cell proliferation (Fig. 2G and H) but didn't show any significant effect on PEV-mediated EC apoptosis (Fig. 2F).

Significant increased TGF- β 1 levels in PEVs from PLWH that had PH compared to non-PH individuals. To assess the alterations in EV numbers and associated TGF- β 1 levels in PLWH with PH, we compared PLWH (n=13) cocaine users or non-users that had PH with PLWH (n=30) and HIV-un-infected (n=30) subjects with and without history of cocaine use that had no PH (Table 1 & 2). PEVs from PLWH+PH subjects were significantly higher in number compared to PLWH without PH (Fig. 3A), even after adjusting for gender and race (Table 2). Although, PLWH-PH PEVs showed no significant difference on apoptosis of HPMECs when compared to EVs from PLWH without PH (Fig. 3Bi), augmented proliferation of endothelial and smooth muscle cells was observed with PLWH-PH PEVs (Fig. 3Bii and C). Interestingly, presence of PH among PLWH was associated with a significantly higher levels of both active and total TGF β -1 in PEVs (Fig. 3D) before and after adjusting for covariates (Table 2). Increased EC and SMC proliferation by EVs from PLWH with PH was also found to be TGF β dependent (Supplementary figure I A-C).

While the EV number and TGF- β 1 levels in PLWH with PH were also significantly high when compared with UI controls, not much difference was observed between PLWH non-PH and UI groups (Supplementary Table D). Importantly, a significant positive correlation of both active and total isoforms of TGF- β levels in EVs was observed with PASP but not with DL_{CO} in PLWH (Fig. 3E, Supplementary fig. I-D and Table 3). Furthermore, significant association of

TGF- β 1 level in EVs was observed with CD4 cell count but not with viral load (Fig. 3E , Supplementary fig. I-D and Table 3).

Increased TGF- β 1 levels in EVs released by HIV-infected monocyte-derived macrophages on exposure to cocaine correspond to augmented endothelial and smooth muscle dysfunction. In light of recent findings demonstrating circulating blood monocytes as a source of perivascular macrophages surrounding the remodeled vessels in PH (7, 8, 11) we next examined the levels of TGF- β 1 in EVs released by HIV-infected monocyte derived macrophages (MDM) in the presence and absence of cocaine. Similar to plasma EVs, we observed significant increase in both active and total forms of TGF β -1 in the EVs from supernatants of HIV-infected MDMs on cocaine treatment (H+C) (Fig. 4A).

Exposure of HPMECs to H+C MDM-EVs lead to a significant increase in apoptosis at 24h and 48h post-treatment as compared to cells treated with EVs derived from un-infected (Con), HIV-infected (HIV) or cocaine-treated (Coc) MDMs (Fig. 4Bi and Supplementary fig. II-B). Besides, a significant endothelial proliferation of apoptosis resistant HPMECs was observed on treatment with H+C MDM-EVs when compared with all other groups at 48h and 96h (Fig. 4Ci & Supplementary figure II-C). However, addition of MDM-EVs in the presence of TGF β -R1 inhibitor resulted in significant abrogation of H+C MDM-EV mediated induction of endothelial apoptosis (Fig. 4Bii) and proliferation (Fig. 4Cii) along with the prevention of SMAD2 activation (Fig. 4D).

Similarly, H+C MDM-EV mediated hyper-proliferation of smooth muscle cells was observed to be TGF- β dependent (Fig. 4E). In parallel, increased expression of phosphorylated-

SMAD2 on treatment with H+C MDM-EVs attenuated on pretreatment of cells with TGF β -R1 inhibitor (Fig. 4F).

Right ventricle dysfunction in rats treated with HIV-cocaine MDM-EVs. To see the *in-vivo* effect of H+C MDM-EVs in the development of PH, we first confirmed the cellular uptake of PKH67-labeled human MDM-EVs by rat cells (Supplementary figure III-A) and *in vivo* bio-distribution of intravenously injected DiR-labeled human MDM-EVs in rat lungs (Supplementary figure III-B). Next, we investigated the effect of H+C MDM-EVs on hemodynamics in WT rats and whether they can further potentiate the RV dysfunction in our previously established non-infectious HIV-Tg rat PAH model (10). We observed a significant increase in the right ventricular systolic pressure (RVSP) ($p=0.003$; unpaired t-test) in WT rats given H+C-EVs compared to rats given uninfected MDM-EVs (Con-EVs). However, comparison between multiple groups (Figure 5B) revealed significant increase in RVSP in only HIV-Tg rats treated with either Con-EVs or H+C-EVs when compared to WT-Con EV group. Interestingly, RVSP in HIV-Tg rats given H+C-EVs exhibited higher trend compared to HIV-Tg rats given Con-EVs and a significant increase compared to WT rats administered H+C-EVs. But assessment of Fulton Index (RV/LV+Septum) showed significant RV hypertrophy only in HIV-Tg rats that were given Con-EVs and only increased trend in HIV-Tg rats given H+C-EVs when compared to the WT groups (Fig. 5C). The trichrome staining of right ventricles exhibited maximum fibrosis and collagen deposition in HIV-Tg rats administered H+C-EVs (Fig. 5E) and no significant differences were observed in the mean arterial pressure (MAP) among all four groups (Fig. 5D). Furthermore, HIV-Tg rats treatment with H+C-EVs resulted in significant increased levels of serum endothelin-1 (ET-1) and tumor necrosis factor- α (TNF- α) along with

increased trend of C-reactive protein (CRP) compared to WT and HIV-Tg rats treated with Con-EVs (Fig. 5F). However, no differences were observed in IL-6 levels (Fig. 5F). Both ET-1 and TNF- α levels had a significant positive correlation with RVSP as shown in Figure 5G.

Myocardial injury in rats treated with HIV-cocaine MDM-EVs. Given that we observed no further increase in Fulton index in HIV-Tg rats on administration of H+C-EVs compared to Con-EVs, we separately compared RV and LV+septum mass with body weight. Though the body weight remained constant in WT rats or HIV-Tg rats injected with Con-EVs or H+C-EVs (Supplementary figure IVA), both WT and HIV-Tg rats that were administered H+C-EVs had decreased RV and LV+septum mass (Fig. 6A-B). However, the effect on RV mass was far less compared to decrease in LV+septum mass (22-30% RV vs. 60-70% LV) among H+C-EV treated rats. This was associated with significantly increased caspase-3 expression in whole LV lysates (Fig. 6D), but not in RV lysates (Fig. 6C) from HIV-Tg rats treated with H+C-EVs when compared to rats treated with Con-EVs. Interestingly, significant increase in caspase-3 expression was observed in RV from WT rats given H+C-EVs compared to WT rats treated with Con-EVs (Fig. 6C). Decrease in both RV and LV cardiomyocyte size in HIV-Tg rats treated with H+C-EV compared to HIV-Tg rats given Con-EVs (Fig 6E-F) further suggested cardiac atrophy of HIV-Tg rats in response to treatment with H+C MDM-EVs. Finally, serum levels of cardiac Troponin-I (cTnI), an indicator of cardiomyocyte damage were increased in HIV-Tg animals given H+C-EVs compared to Con-EVs treated rats (Fig. 6G) and were found to positively correlate with RVSP (Fig. 6H).

Enhanced pulmonary endothelial injury and smooth muscle cell hyperplasia in rats administered with HIV-cocaine MDM-EVs. Staining of lung sections for vWF and α -SMA

indicated enhanced smooth muscle positivity (red fluorescence) in the pulmonary vessels of HIV-Tg rats injected with Con-EVs or H+C-EVs as compared to both groups of WT rats. Increased SMA-positive pulmonary vessels was also found in WT rats injected with H+C-EVs when compared with WT rats given Con-EVs (Fig. 7A). Concordantly, RPASMCs from HIV-Tg rats injected with H+C-EVs exhibited significant hyper-proliferation as early as day 4 of serum-stressed conditions compared to HIV-Tg or WT rats given Con-EVs (Fig. 7B). At day 6 of serum-starvation, RPASMCs from both HIV-Tg rats and WT rats given H+C-EVs exhibited hyper-proliferation when compared to WT Con-EV treated rats. Simultaneously, RPASMCs from HIV-Tg rats showed less apoptotic cell death compared to WT rats at 48h of serum-starvation (Supplementary figure IV-B). These findings corresponded with increased TGF β -R1 activation in RPASMCs (Fig. 7C) and downstream p-SMAD2 expression (Supplementary figure IV-C) from H+C-EV treated rats compared to rats given Con-EVs.

Contrary to RPASMCs, RPMECs from HIV-Tg rats given H+C-EVs demonstrated significantly higher apoptosis in response to serum-starvation when compared with other groups (Fig. 7D) and exhibited high activated caspase-3 (Supplementary figure IV-D). In addition, these ECs exhibited less survivability to serum-starvation (Supplementary figure IV-E) and increased TGF β -R1 (Fig. 7E) and SMAD2 activation (Supplementary figure IV-F).

Pharmacological inhibition of TGF β -R1 resulted in attenuation of HIV-cocaine MDM-EVs mediated cardiopulmonary dysfunction. For *in-vivo* inhibition of TGF- β downstream signaling, we treated rats with GW788388 that is considered to be more potent TGF β -R1 (Alk-5) inhibitor compared to SB431542 without having any non-specific effects on bone morphogenetic protein receptor (BMPR)-2 signaling. Animals from both WT and HIV-Tg groups pre-treated with

GW788388 showed improvement in H+C-EV mediated increase in RVSP (Fig. 8A). Echocardiography performed on this set of rats revealed an increase in RV end-diastolic area (EDA) after 21 days of treatment with H+C-EVs whereas blocking of TGF- β RI prevented this increase (Fig. 8B) as also shown by a significant drop in differences between RV/LV EDA assessed at day 21 and at day 0 (Fig. 8C). Correspondingly, significant increase in the difference between RV/LV ejection fraction (EF) pre- and post- treatment was observed in WT and HIV-Tg rats treated with H+C-EVs in the presence of inhibitor compared to H+C-EVs rats treated with vehicle (Fig. 8D). A parallel mitigation of H+C-EV mediated increase in the levels of ET-1, TNF- α and cardiotroponin I was also observed on treatment with GW788388 (Fig. 8E).

DISCUSSION

In this study, we report a higher number of TGF- β loaded EVs in the plasma from HIV-PH individuals compared to plasma from HIV-non PH individuals, suggesting its potential as a biomarker for HIV-PH. We showed that the EVs from plasma of HIV-infected cocaine users and from HIV-infected MDMs treated with cocaine augment pulmonary endothelial injury and smooth muscle hyperplasia via activation of TGF- β 1 signaling. We show for the first time that the EVs derived from HIV-infected cocaine MDMs can cause pulmonary vascular remodeling and promote the development of PH *in-vivo*.

PAH has been well-established as a secondary complication to HIV infection. The link between HIV infection leading to pulmonary vascular remodeling (6, 9) and further contribution of IVDU in exacerbating the development of PAH has been well-established (26-28). Viral proteins show an additive effect with illicit drugs such as cocaine and opioids in potentiating pulmonary vascular remodeling and development of PH in infectious non-human primate or non-

infectious HIV-transgenic rat models (9, 10, 29). Recently, EVs have been recognized as novel communicators between cells and thereby contributing to disease pathogenesis. Importantly, we and others have shown that the level and content of EVs released by immune cells changes with virus replication (15, 19). Many studies have reported increased levels of plasma- or platelet-derived EVs in patients with idiopathic, heritable or connective tissue disease-associated PAH (15, 21, 30). Here, we show increased number of small-sized PEVs in HIV-PH individuals not only compared to un-infected individuals, but also significantly higher compared to HIV-infected individuals without PH. Furthermore, consistent with our earlier findings of augmented pulmonary vascular damage in response to the dual hit of drug abuse and HIV-infection, we observed higher number of PEVs in HIV-infected cocaine users compared to HIV-infected non-drug users or un-infected cocaine users.

Inflammation is the hallmark feature of all forms of PAH with increased infiltration of inflammatory cells such as macrophages and T-cells surrounding the pulmonary vessels (7, 8, 12). We previously demonstrated significant perivascular inflammation in morphine-treated simian human immunodeficiency virus (SHIV) infected macaques as well as in HIV-Tg rats exposed to cocaine (9). Similarly increased numbers of pro-inflammatory and pro-fibrotic monocytes have been observed in the peripheral blood (31) of SHIVnef- or SIV-infected macaques. Although these studies suggest the association of inflammation with HIV-PAH, studies defining the direct role of inflammatory cells in the development of the disease are limited. Our current study demonstrates the direct effect of EVs derived from HIV-infected monocyte derived macrophages in causing cardio-pulmonary dysfunction.

Macrophage depletion has been reported to prevent the development of PH in animals (32). Recent study by Florentin et al reported that increased number of blood monocytes during

PAH get recruited to lung perivascular spaces and differentiate into inflammatory macrophages responsible for pulmonary vascular remodeling (33). Our pivotal findings suggest that the altered cargo within the circulating EVs derived from H+C-MDMs are able to cause EC injury and SMC proliferation, consequently leading to the development of PH in WT rats. In addition, these H+C MDM-EVs potentiated the vascular damage in the HIV Tg-cocaine rat model of PAH (10) along with increasing serum levels of TNF- α and endothelin-1 known to affect the vascular cell function and facilitate the development of PH (34) (35). Previous studies on PEVs from monocrotaline-induced PAH mice have shown to cause PAH when injected into healthy mice (15, 16). However, EVs are known to transfer their contents not only to different cell types, but also across different species (36, 37). Our data show that injecting HIV-infected human cell-derived EVs into HIV-Tg rats can be used as a tool to delineate the relationship between immune activation/inflammation and non-AIDS comorbidities in this non-infectious HIV-Tg rat model.

Although administration of H+C-EVs in WT and HIV-Tg rats resulted in increased RVSP, analysis of right and left ventricles indicated a significant decrease in LV+septum mass. LV dysfunction with decreased left ventricular mass index has been reported earlier in HIV-infected individuals (38). Changes in rat LV mass can be explained due to inter-ventricular dependence as a result of RV overload associated with high pulmonary vascular resistance (PVR) (39), (40, 41). Other possibility could be the direct effect of H+C EVs on cardiomyocytes leading to increased apoptosis and atrophy. We observed increased levels of circulating cardiac troponin I, CRP and TNF- α indicative of cardiac injury and inflammation in response to H+C-EV treatment, but without an increase in pro-inflammatory IL-6.

TGF- β 1, a growth factor and pro-inflammatory cytokine is known to play an important role in pulmonary vascular remodeling and PH (22, 42, 43). We found that cocaine exposure not

only augmented the levels of TGF- β in the PEVs from PLWH and EVs from HIV-infected MDMs, but also increased the levels in EVs independent of infection. Pre-treatment of cells with TGF- β receptor inhibitor resulted in attenuation of H+C PEV/MDM-EV mediated pulmonary vascular dysfunction. Recent reports demonstrated that TGF β -1-associated exosomes promote more potent and sustained activation of downstream signaling compared to free TGF- β 1 (25). Our findings showing TGF- β dependent escalation of cardio-pulmonary dysfunction in H+C-EV treated rats further emphasizes its significance in EV-mediated pathological changes. However, TGF- β 1 may not be the only molecule and additional cargo molecules including other proteins and miRNAs in these EVs may also contribute to pulmonary vascular remodeling *in-vivo*. We earlier reported that increased levels of miR-130 in H+C-MDM EVs mediates pro-survival signaling in HPASMCs (21). However, we were unable to detect miR-130 in PEVs from any of the groups tested. Nevertheless, higher TGF- β levels in the plasma-EVs from HIV-PH individuals compared to HIV-infected non-PH individuals and its significant correlation with PASP and ability to cause EC/SMC proliferation highlight the importance of TGF- β -rich EVs in PH development.

The exoEasy method that we used to isolate PEVs has recently been reported to be most practical, faster and reproducible over traditional approaches to isolate good quality EVs from small volume serum or plasma samples for the downstream application (44). Nevertheless, our study includes limitations of analyzing only total number of plasma EVs without defining the nature and origin of PEVs. Other limitations include a small sample size and lack of confirmation of PH using right heart catheterization in PLWH. Further investigations using a larger cohort are needed to better characterize the EVs and confirm the correlation of TGF β -loaded EVs with the clinical parameters of PH to use it as a circulatory biomarker of HIV-PH.

In summary, we report for the first time the direct effect of HIV-infected macrophage derived small EVs on pulmonary vascular modeling and PH development via modulation of TGF- β signaling in pulmonary SMCs and ECs. Most importantly, this is the first study that correlates increased number of TGF- β 1 linked PEVs with the presence of PH in HIV-infected individuals. It will be interesting to see if these TGF- β rich plasma-EVs are also high in other forms of PH. Further investigations of these EVs to elucidate their potential as biomarker and therapeutic target for PH are warranted.

ACKNOWLEDGMENTS

Authors are grateful to Dr. Ghazwan Butrous, University of Kent, Canterbury, UK for providing invaluable feedback and critical evaluation of this manuscript. We acknowledge Julie Allen, Department of Molecular and Integrative Physiology, KUMC for helping in animal surgery; Michael Wulser, Department of Internal Medicine, KUMC for morphometric analysis and; Pranjali Dalvi and Himanshu Sharma, Department of Internal Medicine, KUMC for initial standardization of *in-vitro* EV uptake and proliferation/apoptosis experiments. We also acknowledge Electron Microscope Research Laboratory (NIH/NIGMS COBRE grant P20GM104936 and NIH grant 1S10RR027564) for TEM analysis.

FUNDING SOURCES

The funds to carry out the study were provided by National Institute of Health (NIH) grants R01 DA042715, R01 DA034542, R01 HL129875 awarded to N.K.D and R01HL125049, R01 HL120398 to A.M.

FIGURE LEGENDS

Figure 1: Analysis of plasma derived extracellular vesicles (PEVs) from HIV-infected and/or cocaine treated individuals.

Extracellular vesicles were isolated from 0.5ml of EDTA-plasma of HIV-uninfected healthy controls (UI), HIV-uninfected cocaine users (Coc), people living with HIV (PLWH) non drug users and PLWH cocaine users (PLWH+Coc) (n=15/group) using exoEasy kit. **A-C**, Particles were counted and characterized for size distribution by NanoSight nanoparticle tracking analysis. Data represents number of EVs/ml of final EV suspension obtained from 0.5ml EDTA plasma using exoEasy kit. Boxes in B panel depicts median and IQR, whiskers show 10-90 percentiles. **D-E**, Characterization of PEVs by Transmission electron microscopy (TEM) and western blot analysis. Representative TEM image of PEVs at 5000X magnification (C) and western blot of PEV protein extract from three different subjects for exosomal markers (D). ***p<0.001, *p<0.05 vs. UI, # p<0.05, ##p<0.01, ###p<0.001 vs. Coc, \$\$\$ p<0.001 vs. PLWH.

Figure 2: Increased levels of TGF- β 1 in plasma-derived EVs from PLWH cocaine users promote pulmonary endothelial and smooth muscle dysfunction.

Analysis of endothelial apoptosis (**A**) and proliferation (**B**) on treatment with PEVs from HIV-uninfected (UI), HIV-uninfected cocaine users (Coc), people living with HIV (PLWH) non drug users and PLWH cocaine users (PLWH+Coc) (n=15/group). Human pulmonary microvascular endothelial cell (HPMEC) were plated in 96-well plate, serum starved after 24h in 0.5% serum containing media followed by addition of 3 μ g of PEVs/well and analysis of apoptosis using Cell death ELISA after 24h (A) and cell proliferation assay after 48h (B). **C**, Analysis of human pulmonary arterial smooth muscle cell (HPASMC) proliferation on treatment with PEVs. After

72h of plating in 96-well plate, cells were serum starved for 48h, followed by addition of 3 μ g of PEVs/well. MTS cell proliferation assay was performed at 48h post-treatment. **D-E**, Plasma derived EVs (PEVs) were analyzed for active (D) and total (E) TGF β -1 levels by ELISA. **F**, Cell death ELISA on HPMECs treated with PLWH+Coc PEVs in the presence or absence of 10 μ M of SB431542 (TGF β -R1 inhibitor). **G-H**, MTS proliferation assay was performed on HPMECs (G) and HPASMCs (H) after 48h treatment with PLWH+Coc PEVs in the presence or absence of SB431542. n=15/group were used for all experiments Boxes represent median and IQR, whiskers show 10-90 percentiles. ***p<0.001, *p<0.05, vs UI; #p<0.05, ##p<0.01, ### p<0.001 vs Coc; \$\$\$p<0.001 vs PLWH and @@@ p<0.001 vs PLWH+Coc.

Figure 3: TGF- β 1 levels in plasma derived EVs correlate with the presence of PH in HIV-infected individuals.

A, Size distribution (i), and total number (ii) of PEVs were compared between PLWH without PH (n=30) and with PH (n=13) by NanoSight. For this, PEVs from PLWH non drug users (n=15) and PLWH cocaine users (n=15) without PH were grouped as PLWH group (n=30). For PLWH PH group (n=13) plasma samples from PLWH non drug users with PH (n=8) and PLWH cocaine users with PH (n=7) were included (Table 1). **B**, To compare the effect of PEVs from PLWH with PH and without PH on the survival and proliferation of endothelial cells, HPMECs were treated with PEVs from both groups (n=13-15/group) followed by cell death ELISA (i) and MTS assay (ii) at 24h and 48h post-treatment. **C**, Cell proliferation analysis of quiescent HPASMCs treated with PEVs from PLWH with PH and without PH at 48h post-treatment. **D**, Levels of active and total TGF β -1 in PEVs as analyzed by ELISA. **E**, Correlation analysis of EV numbers with the levels of TGF β 1 (active) and PASP; and of TGF β 1 (active) with PASP and

CD4 cell count. For box and whisker plots boxes represent median and IQR, whiskers show 10-90 percentile. *** $p < 0.001$, ** $p < 0.01$ vs. PLWH.

Figure 4: TGF β -1 levels are up-regulated in EVs from HIV-infected monocyte-derived macrophages (MDMs) on treatment with cocaine resulting in enhanced MDM-EV-mediated endothelial dysfunction and smooth muscle hyperplasia. **A**, EVs isolated from supernatants of Monomac-1-derived macrophages infected with HIV-1_{Bal} for 4 days in the presence (H+C) and absence of cocaine (HIV) or un-infected MDMs treated with (Coc) or without cocaine (UI) were analyzed for active (i) and total (ii) TGF β -1 levels by ELISA. **B**, HPMECs were treated with 4 μ g MDM-EVs followed by cell death ELISA at 24 & 48h post EV addition in the absence (i) or at 48h post EV addition in the presence of TGF β -R1 inhibitor (SB431542) (ii) **C**, MTS assay was performed on HPMECs at 48 or 96h post treatment with MDM-EVs in the absence (i) or at 48 h post EV treatment in the presence of SB431542 (ii). **D**, HPMECs treated with H+C MDM-EVs in the presence and absence of SB431542 were lysed using RIPA buffer at 16 h post-treatment, followed by western blot analysis for phosphorylated and total SMAD2. The graphs represent the densitometry analysis of three independent experiments (mean $\pm$ SEM). **E**, MTS assay was performed on HPASMCs treated with H+C MDM-EVs in the presence and absence of SB431542 at 48h post-treatment. **F**, Western blot analysis of HPASMCs for phosphorylated and total SMAD2 at 1h post treatment. For all inhibitor studies cell were pre-treated with SB431542 (10 μ M) for 30 min before the addition of MDM-EVs on cells. Values of experiments using MDM-EVs are average of 3 independent experiments. *** $p < 0.001$, ** $p < 0.01$, * $p < 0.05$, vs control EVs; ### $p < 0.001$, ## $p < 0.01$ vs Coc

Figure 5: Hemodynamic measurements, right ventricle fibrosis and biomarkers of PH in rats injected with HIV-infected cocaine treated macrophage-derived EVs.

A, Figure showing timeline for the administration of HIV-infected cocaine treated MDM-EVs (H+C EV) in WT/HIV-Tg rats. HIV-Tg/ WT rats injected with EVs from uninfected MDMs (Con EV) were used for comparison. Rats were intravenously injected 4 doses of 10 μ g EVs each at 5 day intervals. **B-D**, Box and whisker plots showing right ventricle systolic pressure (RVSP) (B) Fulton Index (C) and Mean arterial pressure (MAP) measurements (D). **E**, Representative micrographs show RV fibrosis after Masson's trichrome staining on formaldehyde-fixed, paraffin embedded RV sections. Magnification 4X (Scale: 200 μ m). **F**, ELISAs were performed to assess serum levels of endothelin-1, TNF- α ; C-reactive protein (CRP) and IL-6. **G**, Graphs showing correlation of RVSP with Endothelin-1 and TNF- α serum levels in rats. n=6-8 rats per group. Box and whisker plots show the median value and 10-90 percentiles. *** $p < 0.001$, * $p < 0.05$ vs. WT-con EV; # $p < 0.05$ vs. WT-H+C EV, \$ $p < 0.05$ vs. HIV-Tg-con EV.

Figure 6: Analysis of cardiac atrophy in rats injected with EVs from HIV-infected and cocaine treated macrophages.

A-B, Ratio of right ventricle (RV) weight to total body weight (A) and left ventricle (LV)+ septum weight /body weight. (B) for WT and HIV-Tg rats injected with EVs from uninfected monocyte derived macrophages (MDM) (Con-EV) or EVs from HIV-infected and cocaine treated MDMs (H+C-EV). Values are from n=7-8 rats per group. **C-D**, Quantitative RT-PCR

analysis of caspase-3 in the RV (C) and LV (D) tissues from rats (n=6/group). The values are expressed as fold change. **E-F**, Representative micrographs showing RV (E) and LV (F) cardiomyocytes from all 4 groups after Masson's Trichrome staining. Magnification 40X, Scale: 100µm. **G**, ELISA was performed to check the levels of cardiac troponin-1 in rat serum from all groups. Values are from n=7-8 rats per group **H**, Graph showing correlation of RVSP with cardiac troponin-1 levels in rats. For box and whisker plots boxes represent median and IQR, whiskers show 10-90 percentile. ***p<0.001, *p<0.05 vs WT-Con EVs; ###p<0.001, ##p<0.01 vs WT-H+C EVs, \$\$\$p<0.001 vs HIV-Tg-Con EVs.

Figure 7: Pulmonary smooth muscle proliferation and endothelial injury in lungs from rats injected with HIV-infected cocaine treated MDM-EVs.

A, Representative micrographs showing immunofluorescence staining of von Willebrand factor (vWF) (green) and α -smooth muscle actin (α -SMA)(red) in pulmonary vessels of size >100µm, 50-70µm and <30µm in all 4 groups (Scale bar=50µm). **B**, Graph showing percent proliferation of rat pulmonary arterial smooth muscle cells (RPASMCs) isolated from all 4 groups. RPASMCs were cultured in 96-well plates and MTS assay was performed at day 2, 4 and 6 to assess the cell proliferation. **C**, Total extract of RPASMCs (n=3/group) was immune-precipitated (IP) using TGF β -R1 antibody followed by western blot (IB) and detection of phosphorylated and total levels of TGF β -R1. Graphs represent densitometric analysis of n=3 animals per group. **D**, Cell death ELISA on rat pulmonary microvascular endothelial cells (RPMECs) isolated from all 4 groups. RPMECs isolated from left lung lobe were cultured in 96-well plates and the oligonucleosome ELISA was performed at 24 and 48h to assess the cell apoptosis. **E**, IP-western blot and densitometric analysis showing phosphorylated and total levels of TGF β -R1 in

RPMECs. Values are Mean $\pm$ SEM of n=3/group ***p<0.001, **p<0.01, *p<0.05 vs WT-con EVs, #p<0.05 vs WT-H+C EVs, \$p<0.05 vs HIV-Tg-Con EVs.

Figure 8: Attenuation of HIV-infected cocaine treated MDM-EVs mediated cardio-pulmonary dysfunction in the presence of TGF β -RI inhibitor.

HIV-Tg or wild type (WT) rats were intravenously injected 4 doses of H+C MDM-EVs, 10 μ g each at 5 days interval in the presence of treatment with TGF β -Receptor inhibitor: GW788388 (1mg/kg/day) or vehicle, once orally for 21 days (n=5/group). **A**, Right ventricle systolic pressure (RVSP) in WT and HIV-Tg rats given H+C EVs with and without inhibitor in comparison to WT rats treated with control EVs. **B**. Right ventricle end diastolic area (RVEDA) at day 0 and day 21 for WT and HIV-Tg rats given H+C-EVs in the presence or absence of GW788388. **C-D**. Percentage change in RV/LV, EDA (C) and Ejection Fraction (EF) in rats on treatment with or without GW788388 (D) **E**. ELISAs were performed to assess serum levels of endothelin-1, TNF- α and Cardiac troponin-I. --	---------	---------	---------	--	--	--	--

Differences among the three groups were assessed using ANOVA followed by post hoc pairwise tests with multiple comparison adjustments. For the covariates adjusted analyses, linear models were used followed by post hoc pairwise tests. For variables, present in only two groups (CD4, Viral load and PASP) t-tests were used.

Abbreviations: CD4, CD4 T-lymphocyte count; FVC, forced vital capacity; FEV, Forced expiratory volume; DL_{CO}, Diffusing capacity for carbon monoxide; % = percent-predicted; BD: bronchodilator test; PASP, pulmonary artery systolic pressure; EV, extracellular vesicles; TGF, Transforming growth factor.

Table 3: Correlation analyses of clinical characteristics with EV number and TGF β levels (total and active) in PLWH and HIV-uninfected individuals.

Figure 1

It is made available under a [CC-BY-NC-ND 4.0 International license](#).

Figure 1: Analysis of plasma derived extracellular vesicles (PEVs) from HIV-infected and/or cocaine treated individuals.

Extracellular vesicles were isolated from 0.5ml of EDTA-plasma of HIV-uninfected healthy controls (UI), HIV-uninfected cocaine users (Coc), people living with HIV (PLWH) non drug users and PLWH cocaine users (PLWH+Coc) (n=15/group) using exoEasy kit. **A-C**, Particles were counted and characterized for size distribution by NanoSight nanoparticle tracking analysis. Data represents number of EVs/ml of final EV suspension obtained from 0.5ml EDTA plasma using exoEasy kit. Boxes in B panel depicts median and IQR, whiskers show 10-90 percentiles. **D-E**, Characterization of PEVs by Transmission electron microscopy (TEM) and western blot analysis. Representative TEM image of PEVs at 5000X magnification (C) and western blot of PEV protein extract from three different subjects for exosomal markers (D). ***p<0.001, *p<0.05 vs. UI, #p<0.05, ##p<0.01, ###p<0.001 vs. Coc, \$\$\$ p<0.001 vs. PLWH.

Figure 2

Figure 2: Increased levels of TGF- β 1 in plasma-derived EVs from PLWH cocaine users promote pulmonary endothelial and smooth muscle dysfunction.

Analysis of endothelial apoptosis (**A**) and proliferation (**B**) on treatment with PEVs from HIV-uninfected (UI), HIV-uninfected cocaine users (Coc), people living with HIV (PLWH) non drug users and PLWH cocaine users (PLWH+Coc) (n=15/group). Human pulmonary microvascular endothelial cell (HPMEC) were plated in 96-well plate, serum starved after 24h in 0.5% serum containing media followed by addition of 3 μ g of PEVs/well and analysis of apoptosis using Cell death ELISA after 24h (**A**) and cell proliferation assay after 48h (**B**). **C**, Analysis of human pulmonary arterial smooth muscle cell (HPASMC) proliferation on treatment with PEVs. After 72h of plating in 96-well plate, cells were serum starved for 48h, followed by addition of 3 μ g of PEVs/well. MTS cell proliferation assay was performed at 48h post-treatment. **D-E**, Plasma derived EVs (PEVs) were analyzed for active (**D**) and total (**E**) TGF β -1 levels by ELISA. **F**, Cell death ELISA on HPMECs treated with PLWH+Coc PEVs in the presence or absence of 10 μ M of SB431542 (TGF β -R1 inhibitor). **G-H**, MTS proliferation assay was performed on HPMECs (**G**) and HPASMCs (**H**) after 48h treatment with PLWH+Coc PEVs in the presence or absence of SB431542. n=15/group were used for all experiments Boxes represent median and IQR, whiskers show 10-90 percentiles. ***p<0.001,*p<0.05, vs UI; #p<0.05,##p<0.01, ### p<0.001 vs Coc; \$\$\$p<0.001 vs PLWH and @@@ p<0.001 vs PLWH+Coc.

Figure 3

Figure 3: TGF- β 1 levels in plasma derived EVs correlate with the presence of PH in HIV-infected individuals.

A, Size distribution (**i**), and total number (**ii**) of PEVs were compared between PLWH without PH (n=30) and with PH (n=13) by NanoSight. For this, PEVs from PLWH non drug users (n=15) and PLWH cocaine users (n=15) without PH were grouped as PLWH group (n=30). For PLWH PH group (n=13) plasma samples from PLWH non drug users with PH (n=8) and PLWH cocaine users with PH (n=7) were included (Table 1). **B**, To compare the effect of PEVs from PLWH with PH and without PH on the survival and proliferation of endothelial cells, HPMECs were treated with PEVs from both groups (n=13-15/group) followed by cell death ELISA (**i**) and MTS assay (**ii**) at 24h and 48h post-treatment. **C**, Cell proliferation analysis of quiescent HPASMCs treated with PEVs from PLWH with PH and without PH at 48h post-treatment. **D**, Levels of active and total TGF β -1 in PEVs as analyzed by ELISA. **E**, Correlation analysis of EV numbers with the levels of TGF β 1 (active) and PASP; and of TGF β 1 (active) with PASP and CD4 cell count. For box and whisker plots boxes represent median and IQR, whiskers show 10-90 percentile. ***p<0.001, **p<0.01 vs. PLWH.

Figure 4

Figure 4: TGFβ-1 levels are up-regulated in EVs from HIV-infected monocyte-derived macrophages (MDMs) on treatment with cocaine resulting in enhanced MDM-EV-mediated endothelial dysfunction and smooth muscle hyperplasia. **A**, EVs isolated from supernatants of Monomac-1-derived macrophages infected with HIV-1_{Bal} for 4 days in the presence (H+C) and absence of cocaine (HIV) or un-infected MDMs treated with (Coc) or without cocaine (UI) were analyzed for active (i) and total (ii) TGFβ-1 levels by ELISA. **B**, HPMECs were treated with 4 μg MDM-EVs followed by cell death ELISA at 24 & 48h post EV addition in the absence (i) or at 48h post EV addition in the presence of TGFβ-R1 inhibitor (SB431542) (ii). **C**, MTS assay was performed on HPMECs at 48 or 96h post treatment with MDM-EVs in the absence (i) or at 48 h post EV treatment in the presence of SB431542 (ii). **D**, HPMECs treated with H+C MDM-EVs in the presence and absence of SB431542 were lysed using RIPA buffer at 16 h post-treatment, followed by western blot analysis for phosphorylated and total SMAD2. The graphs represent the densitometry analysis of three independent experiments (mean±SEM). **E**, MTS assay was performed on HPASMCs treated with H+C MDM-EVs in the presence and absence of SB431542 at 48h post-treatment. **F**, Western blot analysis of HPASMCs for phosphorylated and total SMAD2 at 1h post treatment. For all inhibitor studies cell were pre-treated with SB431542 (10μM) for 30 min before the addition of MDM-EVs on cells. Values of experiments using MDM-EVs are average of 3 independent experiments. ***p<0.001, **p<0.01,*p<0.05, vs control EVs; ###p<0.001, ## p<0.01 vs Coc EVs; \$\$\$p<0.001, \$\$ p<0.01 vs HIV EVs and @@@ p<0.001, @@p<0.01, @p<0.05 vs H+C EVs.

Figure 5

Figure 5: Hemodynamic measurements, right ventricle fibrosis and biomarkers of PH in rats injected with HIV-infected cocaine treated macrophage-derived EVs.

A, Figure showing timeline for the administration of HIV-infected cocaine treated MDM-EVs (H+C EV) in WT/HIV-Tg rats. HIV-Tg/ WT rats injected with EVs from uninfected MDMs (Con EV) were used for comparison. Rats were intravenously injected 4 doses of 10 μ g EVs each at 5 day intervals. **B-D**, Box and whisker plots showing right ventricle systolic pressure (RVSP) (**B**) Fulton Index (**C**) and Mean arterial pressure (MAP) measurements (**D**). **E**, Representative micrographs show RV fibrosis after Masson's trichrome staining on formaldehyde-fixed, paraffin embedded RV sections. Magnification 4X (Scale: 200 μ m). **F**, ELISAs were performed to assess serum levels of endothelin-1, TNF- α ; C-reactive protein (CRP) and IL-6. **G**, Graphs showing correlation of RVSP with Endothelin-1 and TNF- α serum levels in rats. n=6-8 rats per group. Box and whisker plots show the median value and 10-90 percentiles. ***p<0.001, *p<0.05 vs. WT-con EV; #p<0.05 vs. WT-H+C EV, \$p<0.05 vs. HIV-Tg-con EV.

Figure 6

Figure 6: Analysis of cardiac atrophy in rats injected with EVs from HIV-infected and cocaine treated macrophages.

A-B, Ratio of right ventricle (RV) weight to total body weight (A) and left ventricle (LV)+ septum weight /body weight. (B) for WT and HIV-Tg rats injected with EVs from uninfected monocyte derived macrophages (MDM) (Con-EV) or EVs from HIV-infected and cocaine treated MDMs (H+C-EV). Values are from n=7-8 rats per group. **C-D**, Quantitative RT-PCR analysis of caspase-3 in the RV (C) and LV (D) tissues from rats (n=6/group). The values are expressed as fold change. **E-F**, Representative micrographs showing RV (E) and LV (F) cardiomyocytes from all 4 groups after Masson's Trichrome staining. Magnification 40X, Scale: 100µm. **G**, ELISA was performed to check the levels of cardiac troponin-1 in rat serum from all groups. Values are from n=7-8 rats per group **H**, Graph showing correlation of RVSP with cardiac troponin-1 levels in rats. For box and whisker plots boxes represent median and IQR, whiskers show 10-90 percentile. ***p<0.001, *p<0.05 vs WT-Con EVs; ###p<0.001, ##p<0.01 vs WT-H+C EVs, \$\$\$p<0.001 vs HIV-Tg-Con EVs.

Figure 7

Figure 7: Pulmonary smooth muscle proliferation and endothelial injury in lungs from rats injected with HIV-infected cocaine treated MDM-EVs.

A. Representative micrographs showing immunofluorescence staining of von Willebrand factor (vWF) (green) and α -smooth muscle actin (α -SMA)(red) in pulmonary vessels of size $>100\mu\text{m}$, $50\text{--}70\mu\text{m}$ and $<30\mu\text{m}$ in all 4 groups (Scale bar= $50\mu\text{m}$). **B,** Graph showing percent proliferation of rat pulmonary arterial smooth muscle cells (RPASMCs) isolated from all 4 groups. RPASMCs were cultured in 96-well plates and MTS assay was performed at day 2, 4 and 6 to assess the cell proliferation. **C,** Total extract of RPASMCs ($n=3/\text{group}$) was immune-precipitated (IP) using TGF β -R1 antibody followed by western blot (IB) and detection of phosphorylated and total levels of TGF β -R1. Graphs represent densitometric analysis of $n=3$ animals per group. **D,** Cell death ELISA on rat pulmonary microvascular endothelial cells (RPMECs) isolated from all 4 groups. RPMECs isolated from left lung lobe were cultured in 96-well plates and the oligonucleosome ELISA was performed at 24 and 48h to assess the cell apoptosis. **E,** IP-western blot and densitometric analysis showing phosphorylated and total levels of TGF β -R1 in RPMECs. Values are Mean $\pm$ SEM of $n=3/\text{group}$ *** $p<0.001$, ** $p<0.01$, * $p<0.05$ vs WT-con EVs, # $p<0.05$ vs WT-H+C EVs, \$ $p<0.05$ vs HIV-Tg-Con EVs.

Figure 8

It is made available under a CC-BY-NC-ND 4.0 International license.

Figure 8: Attenuation of HIV-infected cocaine treated MDM-EVs mediated cardio-pulmonary dysfunction in the presence of TGFβ-RI inhibitor.

HIV-Tg or wild type (WT) rats were intravenously injected 4 doses of H+C MDM-EVs, 10μg each at 5 days interval in the presence or absence of TGFβ-Receptor inhibitor: GW788388 (1mg/kg/day) oral treatment for 21 days. **A**, Right ventricle systolic pressure (RVSP) in WT and HIV-Tg rats given H+C EVs with and without inhibitor in comparison to WT rats treated with control EVs. **B**. Right ventricle end diastolic area (RVEDA) at day 0 and day 21 for WT and HIV-Tg rats given H+C-EVs in the presence or absence of GW788388. **C-D**. Percentage change in RV/LV, EDA (C) and Ejection Fraction (EF) in rats on treatment with or without GW788388 (D) **E**. ELISAs were performed to assess serum levels of endothelin-1, TNF-α and Cardiac troponin-I.
