## Section 1: Pooled cross-sectional analysis specifications (details of empirical strategy)

We built the models up to the fully-adjusted model outlined in the main text. For all models, we ran a set of linear regression models using daily deaths per million as the outcome. Our estimates of interest are the  $\beta$  terms, an estimate of the effect of each individual policy on the outcome. The specifications were as follows:

- 1) Simple unadjusted models. We ran nine separate models estimating the effect of each policy individually

$$Deaths_{it} = \alpha + \beta PStr_i / PTime_i / PMean_i + \varepsilon_{it}$$

Where:

i=country; t= day relative to the day of the first Covid-19 death  
PStr<sub>i</sub>, PTime<sub>i</sub>, and PMean<sub>i</sub> were three sets of policy variables:

PStr<sub>i</sub> for each policy indicated the maximum level of policy stringency (coded as in Table 1) over the policy analysis period (policy period up to first death/ policy period up to 14-days post-first death)

PTime<sub>i</sub> for each policy indicated the categorical variable for introduction timing (for the policy period up to first death: 0=not introduced over period, 1=introduced 0-10 days before first death, 2=11-20 days before first death, 3=20+ days before first death; for the policy period up to 14-days post-first death: 0=not introduced over period, 1=introduced before first death, 2=introduced 0-7 days after first death, 3=8-14 days after first death)

PMean<sub>i</sub> for each policy was the mean stringency score over the policy analysis period

$\varepsilon_{it}$  was the error term, clustered by country

- 2) Estimate controlling for the effects of all other implemented policies in a single model

$$Deaths_{it} = \alpha + \beta_{1-9} PStr_i / PTime_i / PMean_i + X_i + \varepsilon_{it}$$

Where:

X<sub>i</sub> was the relevant policy variable (PStr/PTime/PMean) for testing and contact tracing policies, to control for differences in Covid-19 death definitions

- 3) Estimate adding date of first case, as a continuous variable, to control for potential virus evolution, and/or advances in scientific understanding over calendar time.

$$Deaths_{it} = \alpha + \beta_{1-9} PStr_i / PTime_i / PMean_i + X_i + \varepsilon_{it}$$

Where:

$X_i$  was date of first death within the country (plus the relevant policy variable [PStr/PTime/PMean] for testing and contact tracing policies), to control for the fact that countries where the outbreak occurred early had less time to prepare

4) Controlling for all additional co-variates, outlined in Table 2 of the manuscript file.

$$Deaths_{it} = \alpha + \beta_{1-9}PStr_i/PTime_i/PMean_i + X_i + \varepsilon_{it}$$

Where:

$X_i$  was a set of country baseline covariates (Table 2, plus the relevant policy variable [PStr/PTime/PMean] for testing and contact tracing policies and date of first case in the country)

5) The fully-adjusted model reported in the main manuscript

$$Deaths_{it} = \alpha + \beta_{1-9}PStr_i/PTime_i/PMean_i + X_i + \delta_t + DoW_{it} + WoY_{it} + \varepsilon_{it}$$

Where:

$\delta_t$  was the day since day of first death (time fixed effect – varied from 0-24/14-38), adjusting for ‘point on the curve’ – relative time  
 $DoW_{it}$  was a set of seven dummies indicating which day of the week is the day t for country i  
 $WoY_{it}$  was a set of dummies indicating the week of the year, both adjusting for seasonality

## Section 2: Scatter plots

### *Policy strictness against cumulative Covid-19 deaths (24-days)*

*Policy timing against cumulative Covid-19 deaths (24-days)*

*Mean policy score (combining strictness and timing, larger score indicates earlier/stricter implementation) against cumulative Covid-19 deaths (24-days; policies implemented before first death)*

*Mean policy score (combining strictness and timing, larger score indicates earlier/stricter implementation) against cumulative Covid-19 deaths (38-days; policies implemented up to 14 days after first death)*

## Section 3: Covid-19 definition check

Shows the attempt to predict the definition of Covid-19 death adopted by mean policy score across the 28 countries where definition has been classified by the European Observatory.<sup>1</sup> There is no statistically significant policy, except for ‘testing policy’ itself which strongly predicts whether a testing definition is used, as expected.

*Table 1: Attempting to predict definition of Covid-19 death from mean policy score (policies enacted prior to first death)*

## Section 4: Regression results

Comparison of coefficient plots for robustness checks

### Mean score (combining timing and strictness)

Main model (linear specification)

Dropping China/Belgium specification

Negative binomial (count model) specification

## Timing alone

### Main model (linear specification)

Estimated effect (daily deaths per 1,000,000)

### Dropping China/Belgium specification

Estimated effect (daily deaths per 1,000,000)

### Negative binomial (count model) specification

Estimated effect (Incidence rate ratio, IRR)

## Strictness alone

### Main model (linear specification)

Estimated effect (Daily deaths per 1,000,000)

### Dropping China/Belgium specification

Estimated effect (Daily deaths per 1,000,000)

### Negative binomial (count model) specification

Estimated effect (Incidence rate ratio, IRR)

## Regression results – linear specifications

*Regression results, mean policy strictness (combination of timing and strictness)*

| Average deaths per day over time period, per million | 24 Days (Policies implemented before first death) |                                |                                |                               |                               | 38 Days (Policies implemented within 14 days after first death) |                               |                               |                               |                              |
