Descriptions of the calculations

(a) The male and female factors were calculated by measuring fold increase in average COVID-19 deaths per million from one decade to the next and taking the average fold increase for the decade spanning 35-44 to the decade spanning 75-84. The decades 15-24 and 25-34 were left out of the calculation as the total deaths were low and the fold increase became relatively

stable after those years. A second source of error derives from the assumption that the individuals in the 10-year groups are evenly distributed for deaths. In the absence of smaller grouping, it is not possible to definitively overcome this at this time.

- (b) For age groupings other than 10 years the base number was calculated by evenly dividing the total deaths by the number of years the group covered. For the 1-4 group the total deaths were divided by 4 and the factor used was 1.
- (c) For 85 and greater, the total deaths were summed and treated as if they were all in the 85-94 range and is further discussed in the text and in Table 4.
