9 **ABSTRACT**

10 Objective: Some retrospective studies reporting epidemiological, clinical
11 characteristics of COVID-19 patients of early stage were published. We aim to provide
12 an overview of epidemiological and clinical characteristics of the COVID-19 patients,
13 and identification, treatment of early stage, especially for the patients with poor
14 prognosis.

15 Data Sources: PubMed, CNKI and Google Scholar.

16 Study Selection: We searched for published retrospective studies that described
17 epidemiological and clinical characteristics of confirmed COVID-19 patients in China
18 by April 14th, 2020 with search terms. Some studies were excluded according to criteria.
19 Finally, 53 studies were included.

20 Data Extraction: Characteristics of the COVID-19 patients available from included
21 articles were extracted, reorganized and recorded into electronic data forms.

22 Data Synthesis: Characteristics of patients in the included studies were summarized and
23 analyzed for median-interquartile ranges and univariable odds ratio.

24 Conclusion: This study summarized, analyzed and compared epidemiological, clinical
25 characteristics and estimated univariable risk factors among confirmed COVID-19

Epidemiological, Clinical Characteristics and Risk Factors for Severe Condition and ICU Admission of COVID-19 Patients of Early Stage in China: A review

patients either in former epicenter, in severe condition, with ICU admission or not of early stage. Higher proportions of patients were found to have older age and more comorbidities, typical characteristics on admission and complications either in former epicenter, with severe condition or ICU admission. No evidence showed that patients who were male or had smoking history had higher susceptibility, but they were significant risk factors for severe condition. Some self-implementable traditional Chinese medicine therapies conducted for immunity improvement, control of comorbidities and reduction of some medicine intake. Limited evidence revealed that some characteristics of the disease might be changing with human-to-human transmission, and more research, especially international collaboration, is needed.

KRY WORDS

COVID-19; Characteristics; Risk factors; Severity; Intensive unit care.

INTRODUCTION

In early December 2019, some cases of pneumonia with unknown cause, identified and named as SARS-Cov-2 later, occurred in Wuhan City, the capital city of Hubei Province (hereinafter former epicenter), China [1]. Results of gene sequence of the virus collected from infected patients showed a high similarity to virus in bats [2], and through haplotype analyses of 93 complete genomes of SARS-CoV-2, the source was identified as not from Huanan Seafood Market but from some other origin(s) [3]. As of April 26th, 2020, a total of 2,804,796 people were confirmed infected with SARS-CoV-2, including 193,710 deaths worldwide [4].

Till April 14th, 2020, over 80 retrospective case series had reported epidemiological and clinical characteristics of COVID-19 patients in or outside of former epicenter at

Epidemiological, Clinical Characteristics and Risk Factors for Severe Condition and ICU Admission of COVID-19 Patients of Early Stage in China: A review

different stages of transmission and scale of location in China. Typical signs and symptoms of COVID-19 patients includes fever, dry cough, myalgia and fatigue, which were found similar to severe acute respiratory syndrome (SARS) with high mortality [5]. Clustering onset of the disease and higher susceptibility among older males with comorbidities were reported [6], and evidence from Li et al indicated that human-to-human transmission had occurred since mid-December 2019 [7]. Some studies reported characteristics of the patients outside former epicenter, indicating relatively mild symptoms among them than in Hubei Province [8,9]. In addition, the confirmed patients sometimes assumed no typical symptoms and radiologic abnormalities [10], and more attention should be paid to hospital-related transmission [12].

In this study, we summarized, analyzed and compared confirmed cases from 53 retrospective studies of early stage in China, involving epidemiological characteristics, clinical outcomes, comorbidities, signs and symptoms on admission, complications, radiologic and laboratory findings on admission and treatment. Based on the 53 retrospective studies, more research was done concerning patients in/outside former epicenter, with/without severe condition and with/without ICU admission in terms of epidemiological and clinical characteristics, and risk factors of patients. Our study could be helpful for researchers and medical workers to have a more comprehensive and dynamic view of the characteristics of the disease of early stage in China.

MATERIALS AND METHODS

Search strategy and selection criteria

We searched PubMed, CNKI and Google Scholar for published retrospective studies that described epidemiological and clinical characteristics of confirmed COVID-19 patients in China by April 14th, 2020. Search terms included “coronavirus”, “COVID”

Epidemiological, Clinical Characteristics and Risk Factors for Severe Condition and ICU Admission of COVID-19 Patients of Early Stage in China: A review

and “2019-nCov” from December 2019 with no language restrictions. We also extensively searched the Internet for other published studies. Case report, research lacking key epidemiological information (e.g., gender or age) or radiological and laboratory findings, report on specific cases (e.g., newborn, familial cluster infections or selected for certain examination), research or data of patients outside China and of suspected were excluded. Finally, 53 studies were included.

Data analysis

Epidemiological and clinical characteristics were summarized, analyzed and compared in/outside former epicenter, with/without severe condition and with/without ICU admission. Categorical variables summarized as percentages were expressed as median and interquartile ranges (IQR), and differences were compared with the Mann-Whitney U test between patients in/outside former epicenter and with/without severe condition. We also explored univariable risk factors of the patients with severe condition or ICU admission in included studies, and Chi-squared test or Fisher’s exact probability test and one-samples T test were used as appropriate. Statistical analyses were performed by SPSS Version 25.0 Software, and P value <0.05 was considered statistically significant with all tests 2-sided.

RESULTS

Overview of studies, epidemiological and clinical characteristics

This study systematically analyzed 53 published retrospective researches since the onset of SARS-CoV-2 as of April 14th, 2020 [5,6,8-58]. Among them, 20 studies were in Chinese [20,23,29-31,44-58], and 33 were in English [5-19,21,22,24-28,32-43]. Details of hospital(s), city/cities, province(s), admission period and number of patients

Epidemiological, Clinical Characteristics and Risk Factors for Severe Condition and ICU Admission of COVID-19 Patients of Early Stage in China: A review

in each study are in table S2.

Epidemiological and clinical characteristics of the 53 studies are in figure 1,2 and table S1 and table S3-S36. Proportions of male were higher than 50% in 34 studies, ranging from 30% to 77% [median=53.45%(48.48%-58.03%,IQR)] in 50 studies compared with other three nationwide studies (51.4%, 57.3% and 58.2%). [median=51.6%(34.65%-62%)] of confirmed patients were aging>45-60 years old, and smoking history was reported in 13 studies [median=7% (6.55%-24%, IQR)], but no evidence shows higher susceptibility for current smokers (table S1). Case fatality rates (CFRs) were [median=0.75%(0%-9.53%,IQR)] in total, and [median=18%(9.6%-32.2%,IQR)] of the confirmed patients were in severe condition.

Results shows that [median=48%(31.08%-58.08%,IQR)] of the patients had at least one comorbidity, and the top 5 comorbidities were hypertension [median=13.7%(6.7%-27.5%,IQR)], diabetes [median=9.6%(5.86%-12%,IQR)], cardiovascular disease [median=5.2%(2.68%-12.25%,IQR)], digestive disease [median=5.1%(3.91%-5.77%,IQR)] and cerebrovascular disease [median=2.8%(2.03%-4.73%,IQR)] (table S1). As for signs and symptoms, the most common one was fever [median=83.15%(76.13%-92.15%,IQR)], followed by cough [median=62.6%(50%-75.38%,IQR)], fatigue [median=31.7%(15.68%-53.93%,IQR)], sputum production [median=18.1%(13%-34.69%,IQR)], chest tightness, myalgia, inappetence, dyspnea, chills and others (table S1). Most complications occurred in about less than 10% of the patients (acute cardiac injury, other acute respiratory injury, acute kidney injury and shock) in addition to ARDS [median=3.2%(0%-18.3%,IQR)] and secondary infection [13.75%(10%-17.5%,IQR)].

Bilateral involvement [median=81.85%(68.81%-92.85%,IQR)], ground glass opacity [median=75%(29.37%-92.15%,IQR)], interlobular septal thickening

Epidemiological, Clinical Characteristics and Risk Factors for Severe Condition and ICU Admission of COVID-19 Patients of Early Stage in China: A review

[median=60.85%(45.25%-77.33%,IQR)], pleural thickening [median=53.8%(12.3%-66.8%,IQR)] and consolidation [median=41.8%(19.45%-49.73%,IQR)] were most commonly radiological findings tested for the patients on admission. As for laboratory findings, they were C-reactive protein > 3-6 mg/L [median=62.86%(52%-83.9%,IQR)], C-reactive protein > 8-10 mg/L [median=60.7%(52%-75.2%,IQR)], lymphocyte count < 0.8-1.5×10⁹/L [median=50.2%(33.6%-62.45%,IQR)], lactate dehydrogenase > 240-250 U/L [median=38.15%(25.56%-63.25%,IQR)], hemoglobin < 110-130 g/L, white blood cell count < 4× 10⁹/L, D-dimer > 0.5 mg/L and procalcitonin > 0.5 ng/mL. Details of other radiological, laboratory findings and treatments are in table S1.

Epidemiological and clinical characteristics of the patients in vs. outside the former epicenter

In our study, 15 studies reported characteristics of COVID-19 patients in former epicenter [5,6,10,12-16,22,24,28,44,45,47,53], 30 in one city or province outside former epicenter [7-9,17-19,26,27,29-31,33,34,36-43,46,49-52,54-58] and five in more than one city, province [20,21,25,35,48] or nationwide (in 30/31 provinces) [11,23,32]. Compared with the patients of studies outside former epicenter, patients in former epicenter were older (age>45-60, y) [median=61.5%(52.95%-68.5%,IQR)] vs [median=34.65%(29.03%-48.53%,IQR)] and had higher proportions of severe cases [median=48.3%(36%-56.2%)] vs. [median=15.7%(7.95%-26.55%,IQR)] , CFRs [median=10.7%(3.68%-15.43%,IQR)] vs. [median=0%(0%-0.73%,IQR)] and comorbidities [median=46.75%(37.1%-53.2%,IQR)] vs. [median=28.6%(18.1%-47.5%,IQR)] significantly (P<0.05), including hypertension, cardiovascular disease and diabetes (table S1). Higher proportions of the patients in former epicenter had apparent signs and symptoms, including fever, highest temperature > 39°C, dyspnea

Epidemiological, Clinical Characteristics and Risk Factors for Severe Condition and ICU Admission of COVID-19 Patients of Early Stage in China: A review

($p < 0.01$), chest tightness, fatigue and inappetence, but fewer patients had headache and in asymptomatic infection in center (table S1). Higher proportions of complications, including ARDS ($p < 0.05$), acute cardiac injury, other acute respiratory injury, acute kidney injury and shock, were reported in the patients in former epicenter. On admission, most radiological and laboratory abnormalities were found in more patients in former epicenter, including significantly ($p < 0.05$) higher proportions of bilateral involvement (chest radiological examination), white blood cell count $> 10 \times 10^9/L$, lactate dehydrogenase $> 240-250$ U/L, C-reactive protein $> 3-6$ mg/L and C-reactive protein $> 8-10$ mg/L (Table S1). Invasive/non-invasive mechanical ventilation and ICU care were applied to higher proportions of the patients in former epicenter significantly ($p < 0.05$).

Characteristics and univariable risk factors among patients in severe condition/ICU admission

Epidemiological and clinical characteristics of the COVID-19 patients were furtherly divided into ICU/ non-ICU groups in two studies [5, 12], and into severe/ non-severe groups in 20 studies [10,11,15,17,21,24-26,29,33,35,37-39,43,44,49,51,53,55] (table S37-S41).

Proportions of male, age $> 45-60$ and comorbidities including hypertension, diabetes, cardiovascular disease and COPD were significantly higher in patients with severe condition ($p < 0.05$, table S37), together with some signs, symptoms, radiological and laboratory findings on admission including dyspnea, lactate dehydrogenase $> 225-250$ U/L, bilateral involvement (radiological) and pleural effusion (radiological).

ICU cares were required in [median=13.75%(1.5%-24.15%,IQR)] of the patients, and risk factors ($p < 0.05$) of them included hospitalized patients, with some comorbidities including hypertension, cerebrovascular disease and diabetes, with some clinical

Epidemiological, Clinical Characteristics and Risk Factors for Severe Condition and ICU Admission of COVID-19 Patients of Early Stage in China: A review

characteristics including cough, dyspnea, sore throat, dizziness, respiratory rate >24 breaths/ min, white blood cell count $> 10 \times 10^9/L$, hypersensitive troponin I > 28 pg/mL (99th percentile) and procalcitonin ≥ 0.5 ng/mL (table S39). Details of univariable risk factors of the patients with severe condition/ICU admission are in table S39, and characteristics among patients with severe condition/ICU admission are in table S37.

DISCUSSION

Results of our study showed that over half of the confirmed COVID-19 patients were middle-aged and older male, with more cases of older people in former epicenter. Proportions of the male patients in our study were higher than the male population in China ($t=2.36$, $p=0.022$) as of 2019 (51.08%) and in Wuhan ($t=1.03$, $p=0.32$) as of 2017 (51%) [59, 60]. 14 studies reported 0%-48% of medical staff infection with relative milder prognosis ($p<0.05$). As of Feb 11th, 2020, a total of 1716 (3.8%) medical staff were infected with SARS-CoV-2, with death rate at 0.4%, six deaths in China [23]. One study was about two death cases of old male with a long smoking history but no previous chronic underlying disease [6]. [median=7%(6.55%-24%,IQR)] of confirmed patients had smoking history, lower than the proportion of current smokers (> 15 y, 27.7%) in China by 2015 markedly ($t=-4.35$, $p<0.002$) [26]. However, higher percentages of former smokers were reported in patients with severe condition than non-severe [median=6.9%(5.2%-25%,IQR)] vs. [median=3.7%(1.3%-17%,IQR)], and it was also connected with severe condition significantly ($p>0.05$). This may be because of significantly higher ACE2 gene expression in lungs of former smokers, which is receptor for SARS-CoV-2 [62]. CFRs were [median=10.7%(3.68%-15.43%,IQR)] in former epicenter and [median=0%(0%-0.73%,IQR)] outside according to included

Epidemiological, Clinical Characteristics and Risk Factors for Severe Condition and ICU Admission of COVID-19 Patients of Early Stage in China: A review

1 studies, and significantly higher among patients with severe condition
2 [median=6.5%(1.3%-17%,IQR)] vs. [median=0%(0%-0.9%,IQR)] and ICU
3 admission (16.7%-38% vs 0%-4%). Epidemiological characteristics including male,
4 age $\geq$ 45-60 and former smoker and hospitalized patients had significant connections
5 with severe condition or ICU admission ($p < 0.05$).

6 Nearly all comorbidities were reported in higher proportions among the patients in
7 former epicenter, severe condition or with ICU admission than not, and some of them
8 were also significant risk factors of severe condition or ICU admission among COVID-
9 19 patients ($P > 0.05$) as a result of relatively poor immunity [6], including hypertension,
10 cardiovascular disease, cerebrovascular disease, cardio-cerebrovascular disease,
11 diabetes, COPD, malignancy, immunosuppression. However, no evidence shows that
12 proportions of the patients with hypertension ($t = -3.12$, $p < 0.01$), cardiovascular disease
13 ($t = -10.68$, $p < 0.01$), cerebrovascular disease ($t = 1.75$, $p = 0.124$), diabetes ($t = 0.72$,
14 $p = 0.477$) and COPD ($t = -3.07$, $p < 0.01$) in most studies were significantly higher than
15 the national prevalency of China [63-67].

16 However, we noticed that higher proportions of comorbidities, such as
17 immunodeficiency HIV and malignancy, were reported in some non-ICU and non-
18 severe groups, indicating poor immunity. Result of minimally invasive pathological
19 examination by Xu et al also showed that severe immune injury in COVID-19 patients
20 could be caused by overactivation of T cells, partially, manifested by increase of Th17
21 and high cytotoxicity of CD8 T cells [68]. Pulmonary and systemic inflammatory
22 responses associated with coronavirus are triggered by the innate immune system
23 mostly when viruses are recognized, and this type of immune response can also inhibit
24 virus replication, promote virus clearance, induce tissue repair, and trigger a prolonged
25 adaptive immune response against the viruses [69]. As a result, further research is

Epidemiological, Clinical Characteristics and Risk Factors for Severe Condition and ICU Admission of COVID-19 Patients of Early Stage in China: A review

1 needed on how to neutralize harmful immune response and even make it a therapy for
2 COVID-19 patients especially with severe condition or ICU admission.

3 With increasing human-to-human transmission of the virus, more confirmed COVID-
4 19 patients were reported with no typical signs, symptoms, and radiologic, laboratory
5 findings on admission and with milder severity especially for studies outside Hubei.
6 This is most likely because of more patients were diagnosed earlier than those in Hubei
7 at the early stages of the SARS-CoV-2 outbreak. However, we cannot rule out that some
8 of the characteristics and severity of the disease may change with human-to-human
9 transmission. Research of Bai et al and Hu et al indicated that patients under
10 asymptomatic infection may have infectivity of the virus and even become a “super
11 infector” [70; 71]. In addition, there were reports of several cases of positive results or
12 false-negative results of RT-PCR test in diagnosis after discharge from hospital upon
13 treatment for even 5 to 13 days in China and Canada [72; 73; 74].

14 Laboratory findings showed that alanine aminotransferase, aspartate aminotransferase,
15 total bilirubin, creatinine, creatine kinase, lactate dehydrogenase and hypersensitive
16 troponin I of some the COVID-19 patients were beyond normal range, especially of
17 significant relevance for patients with severe conditions or ICU admission, indicating
18 liver, heart and kidney injury caused by SARS-CoV-2 [75-77].

19 Lymphocytes count of more than half of the patients on admission were below the
20 normal range in our study [median=50.2%(33.6%-62.45%,IQR)], especially in severe
21 groups [median=82.1%(71.8%-88.9%,IQR)], which probably had significant
22 connections with disease severity and mortality [78]. Under the requirement of avoiding
23 unnecessary outings and home isolation, some self-implementable traditional Chinese
24 medicine therapies helpful for improving immunity are recommended, including
25 moxibustion, acupressure and some traditional exercises such as the *Tai Chi Chuan*

Epidemiological, Clinical Characteristics and Risk Factors for Severe Condition and ICU Admission of COVID-19 Patients of Early Stage in China: A review

exercise [79-82]. In addition, they can relieve the burden of some comorbidities such as cancer pain, diabetic peripheral neuropathy and asthma [80,83,84] by decreasing duration, frequency or severity. As a result, they can also reduce medication intake, especially those that may have considerable addiction and adverse events (e.g. opioid, lidocaine medicated plaster and oral corticosteroids) [85,86].

Our study had several limitations. Firstly, there might be some repetition among data of patients from the 53 researches included in our study because of the overlap in range of time and location, and a table of some detailed information of the included studies are in table S2. Secondly is the relatively small number of researches included in our study for risk factor analysis among patients with/without ICU admission, so more researches are needed on epidemiological and clinical characteristics of COVID-19 patients with different ICU admission groups. Finally, results of our study are based on published researches, while many issues of SARS-Cov-2 are still uncertain, so there may exist bias in our study which justifies a modest interpretation of our results.

CONCLUSION

This study summarized, analyzed and compared epidemiological, clinical characteristics and estimated univariable risk factors among confirmed COVID-19 patients in/outside former epicenter, with/without severe condition, with/without ICU admission of early stage in China. Higher proportions of patients were found to have older age and more comorbidities, typical characteristics on admission and complications either in former epicenter, with severe condition or ICU admission. No evidence showed that patients who were male or had smoking history had higher susceptibility, but they were significant risk factors for severe condition. Some self-implementable TCM therapies should be recommended for immunity improvement,

Epidemiological, Clinical Characteristics and Risk Factors for Severe Condition and ICU Admission of COVID-19 Patients of Early Stage in China: A review

control of comorbidities and reduction of some medication intake. Limited evidence revealed that some characteristics of the disease might be changing with human-to-human transmission, and more research, especially international collaboration, is needed.

ACKNOWLEDGEMENTS

We thank all the patients and authors involved in the researches included in our study.

Epidemiological, Clinical Characteristics and Risk Factors for Severe Condition and ICU Admission of COVID-19 Patients of Early Stage in China: A review

Figure 1: Epidemiological characteristics, clinical outcomes, common comorbidities, signs and symptoms on admission and complications.

Epidemiological, Clinical Characteristics and Risk Factors for Severe Condition and ICU Admission of COVID-19 Patients of Early Stage in China: A review

1 Legend: This figure demonstrates distribution of proportions among epidemiological
2 characteristics, clinical outcomes, common comorbidities, signs and symptoms on
3 admission and complications of confirmed COVID-19 patients in included studies.
4 Each brown or blue point represents one study conducted in or outside of former
5 epicenter respectively, with lines in same color shows median and interquartile range
6 of each subject (e.g. “Male”, “Age>45-60”) and group (i.e. in or outside of former
7 epicenter). Three studies, Liang 2020 A, Guan 2020 and Zhang 2020 A reported
8 epidemiological and clinical characteristics of the patients nation-widely, and they are
9 listed by lines in each subject for reference accordingly. (A) Smoker*: Includes current
10 or(and) former smokers; Exposure A*: Exposure to the Huanan Seafood Market for
11 studies conducted in former epicenter, and exposure to former epicenter for studies
12 outside of former epicenter; Exposure B: Exposure to confirmed patients. (B) Cardio*:
13 Cardiovascular disease; Cerebro*: Cerebrovascular disease; COPD: Chronic
14 obstructive pulmonary disease; Digest*: Digestive disease; CLD*: Chronic liver
15 disease; Immuno*: immunodeficiency or HIV; CKD*: Chronic kidney disease.
16 (C): >39°C*: The highest temperature >39°C during admission; Sputum*: Sputum
17 production; Tightness*: Chest tightness; Throat*: Sore throat; Asymptomatic*:
18 Asymptomatic infection cases. (D): ARDS: Acute Respiratory Distress Syndrome;
19 ACI*: Acute cardiac injury; oARI*: Other acute respiratory injury; AKI*: Acute kidney
20 injury.

Epidemiological, Clinical Characteristics and Risk Factors for Severe Condition and ICU Admission of COVID-19 Patients of Early Stage in China: A review

Figure 2: Major radiologic, laboratory findings on admission and treatments.

Epidemiological, Clinical Characteristics and Risk Factors for Severe Condition and ICU Admission of COVID-19 Patients of Early Stage in China: A review

1 Legend: This figure demonstrates distribution of proportions among major radiologic,
2 laboratory findings on admission and treatments of confirmed COVID-19 patients in
3 included studies. Each brown or blue point represents one study conducted in or outside
4 of former epicenter respectively, with lines in same color shows median and
5 interquartile range of each subject (e.g. “Bilateral*”, “Local*”) and group (i.e. in or
6 outside of former epicenter). Three studies, Liang 2020 A, Guan 2020 and Zhang 2020
7 A reported epidemiological and clinical characteristics of the patients nation-widely,
8 and they are listed by lines in each subject for reference accordingly. (A): Bilateral*:
9 Bilateral involvement; Local*: Local patchy opacity; GGO: Ground glass opacity;
10 Effusion*: Pleural effusion; Thickening*: Pleural thickening; Interlobular*:
11 Interlobular septal thickening; Paving*: Crazy-paving pattern; Air*: Air bronchogram
12 sign; Lymph node*: Lymph node enlargement. (B): WBC ↑*: White blood cell count >
13 $9.5-10 \times 10^9/L$; WBC ↓*: White blood cell count < $3.5-4 \times 10^9/L$; NE ↑*: Neutrophil
14 count > $5.8-7 \times 10^9/L$; NE ↓*: Neutrophil count < $1.8-2 \times 10^9/L$; Lymphocyte ↓*:
15 Lymphocyte count < $0.8-1.5 \times 10^9/L$; Hb ↓*: Hemoglobin < 110-130g/L; PLT ↓*:
16 Platelet count < $100-150 \times 10^9/L$; D-dimer > 0.5*: D-dimer > 0.5mg/L; ALT > 40-50*:
17 Alanine aminotransferase > 40-50U/L; AST > 40-50*: Aspartate aminotransferase >
18 40-50U/L; LDH > 240-250*: Lactate dehydrogenase > 240-250U/L. (C): TBIL >21-
19 26*: Total bilirubin >21-26 mmol/L; PT >13.5-17: Prothrombin time >13.5-17s; PT <
20 10-10.5*: Prothrombin time <10-10.5s; CK >185-200*: Creatine kinase > 185-200U/L;
21 Cr > 73-87*: Serum creatinine > 73-87μmol/L; Cr > 111-133*: Serum creatinine > 111-
22 133μmol/L; PCT > 0.5*: Procalcitonin > 0.5ng/mL; BUN ↑*: Blood urea nitrogen >
23 7.6-9.5mmol/L; CRP > 3-6*: C-reactive protein > 3-6mg/L; CRP > 8-10*: C-reactive
24 protein > 8-10mg/L. (D): Oxygen*: Oxygen therapy; Invasive*: Invasive mechanical

Epidemiological, Clinical Characteristics and Risk Factors for Severe Condition and ICU Admission of COVID-19 Patients of Early Stage in China: A review

- 1 ventilation; Non-invasive*: Non-invasive mechanical ventilation; CRRT: Continuous
- 2 renal replacement therapy; ECMO: Extracorporeal membrane oxygenation; Antibiotic*:
- 3 Antibiotic treatment; Antiviral*: Antiviral treatment; CS: Corticosteroid therapy; IVIG:
- 4 Intravenous immunoglobulin therapy; Antifungal*: Antifungal treatment; TCM:
- 5 Traditional Chinese medicine; ICU: Intensive care unit care.

Epidemiological characteristics of the confirmed patients in or outside of former epicenter

Comorbidities of the confirmed patients in or outside of former epicenter

Signs and symptoms of the confirmed patients on admission in or outside of former epicenter

Complications of the confirmed patients in or outside of former epicenter

Radiologic findings of the confirmed patients on admission in or outside of former epicenter

Laboratory findings of the confirmed patients on admission in or outside of former epicenter A

Laboratory findings of the confirmed patients on admission in or outside of former epicenter B

Treatment of the confirmed patients in or outside of former epicenter
