28 **Abstract (220 of 220 words)**

29 Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) control in the United States remains
 30 hampered, in part, by testing limitations. We evaluated a simple, outdoor, mobile, colorimetric reverse
 31 transcription loop-mediated isothermal amplification (RT-LAMP) assay workflow where self-collected
 32 saliva is tested for SARS-CoV-2 RNA. From July 16 to November 19, 2020, 4,704 surveillance samples
 33 were collected from volunteers and tested for SARS-CoV-2 at 5 sites. A total of 21 samples tested
 34 positive for SARS-CoV-2 by RT-LAMP; 12 were confirmed positive by subsequent quantitative reverse-
 35 transcription polymerase chain reaction (qRT-PCR) testing, while 8 were negative for SARS-CoV-2
 36 RNA, and 1 could not be confirmed because the donor did not consent to further molecular testing. We
 37 estimated the RT-LAMP assay's false-negative rate from July 16 to September 17, 2020 by pooling
 38 residual heat-inactivated saliva that was unambiguously negative by RT-LAMP into groups of 6 or less
 39 and testing for SARS-CoV-2 RNA by qRT-PCR. We observed a 98.8% concordance between the RT-
 40 LAMP and qRT-PCR assays, with only 5 of 421 RT-LAMP negative pools (2,493 samples) testing
 41 positive in the more sensitive qRT-PCR assay. Overall, we demonstrate a rapid testing method that can
 42 be implemented outside the traditional laboratory setting by individuals with basic molecular biology
 43 skills and can effectively identify asymptomatic individuals who would not typically meet the criteria for
 44 symptom-based testing modalities.

54

55 Introduction

56 More than 340,000,000 severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) diagnostic
 57 tests have been performed in the United States as of February 22, 2021, yet it is estimated that 80-95%
 58 of infected individuals are not tested ^{1,2}. The availability of diagnostic testing for population surveillance
 59 around the United States has been limited because of testing supply shortages and guidelines set by
 60 public health officials ^{3, 4}. Multiple studies have shown that asymptomatic and presymptomatic
 61 individuals infected with SARS-CoV-2 can be as infectious as symptomatic individuals ⁵⁻⁹, with recent
 62 estimates of up to 59% of transmission coming from asymptomatic or presymptomatic individuals ¹⁰.
 63 Virological assessments of SARS-CoV-2-positive individuals and coronavirus disease 2019 (COVID-
 64 19) patients further support the reports of asymptomatic transmission, identifying no significant
 65 differences in viral loads found in the upper respiratory tracts of asymptomatic and symptomatic
 66 individuals ^{5, 7, 11-13}. Furthermore, Arons et al. (2020) demonstrated that positive viral cultures can be
 67 isolated from presymptomatic patients up to 6 days before the onset of symptoms ⁵.

68
 69 Delays in reporting test results can prevent timely isolation of infected individuals. Most current testing
 70 programs fail to identify and efficiently notify infected individuals. Since transmission can occur before
 71 symptoms manifest, reporting delays create a major barrier to safely returning to workplaces and
 72 schools ¹⁴. Therefore, there remains an urgent need for rapid tests that identify presymptomatic and
 73 asymptomatic individuals while conserving diagnostic testing reagents. Non-diagnostic point-of-care
 74 (POC) testing, used in conjunction with the current clinical diagnostic testing regimen, may improve our
 75 ability to identify infectious individuals and limit their exposure to others while they are most contagious
 76 and conserve clinical diagnostic tests for those who require confirmatory testing. Incorporating active
 77 surveillance using POC tests as part of mitigation strategies for reopening K-12 schools could play an
 78 integral role in reducing SARS-CoV-2 transmission among students, teachers and staff members,
 79 families, and the surrounding community ^{15, 16}.

80
 81 Loop-mediated isothermal amplification (LAMP) is a low-cost method for rapid target-specific detection

of nucleic acids¹⁷. LAMP has long been used as an alternative to gold-standard quantitative reverse transcription polymerase chain reaction (qRT-PCR) to surveil populations for a variety of pathogens, especially in resource-limited settings^{18–22}. Reverse transcription LAMP (RT-LAMP) assays have recently been developed for rapid SARS-CoV-2 testing^{23–29}. RT-LAMP is an appealing candidate for POC SARS-CoV-2 testing because it is inexpensive, circumvents supply shortages by relying on different reagents than current diagnostic tests, requires minimal sample processing, and can be deployed outside of traditional laboratory settings. Recently, a number of studies have shown the correlation between the presence of virus in saliva and nasopharyngeal swabs, demonstrating that saliva specimens are a valid and reliable alternative to nasopharyngeal swab specimens for SARS-CoV-2 testing^{30–35}. Saliva specimen self-collection is noninvasive, can be done at home, does not require swabs or personal protective equipment, and limits direct contact between test operators and testing populations. Here we describe our experience implementing a simple, rapid-turnaround, mobile, non-diagnostic SARS-CoV-2 testing workflow combining self-collected saliva and RT-LAMP in volunteers without symptoms of SARS-CoV-2 infection. Individuals were strongly encouraged to isolate and obtain follow-up diagnostic testing after receiving a positive result by RT-LAMP. This addresses a key knowledge gap of how on-site RT-LAMP testing performs in real-world conditions, since virtually all previous studies have only evaluated SARS-CoV-2 RT-LAMP in well-equipped molecular biology laboratories.

Materials and Methods

POC testing sites

To begin operating voluntary POC testing, we developed a system of color-coded storage bins for equipment and supplies, as well as assembled folding tables, chairs, extension cords, and coolers that could be easily decontaminated and packed to fit in a Dodge Caravan (FCA US LLC., Auburn Hills, MI) or other, similarly sized minivan for transportation between testing sites and our base laboratory facility. On July 16, 2020, we launched our first mobile POC testing sites which ultimately expanded over 18 weeks to include two workplaces, two K-12 schools, and an athletics program (Suppl. Table 1). With

the exception of the athletics program, sites were initially outdoors, sometimes under an overhang, but otherwise open to the environment. The athletics site was a climate-controlled, indoor practice field. At all sites, equipment and reagents were transported by minivan and surfaces were disinfected during assembly, breakdown, and frequently throughout testing. Participant consenting and volunteer sample collection were performed on-site but separated from the sample preparation and assay areas (most commonly on the other side of the building). In an effort to limit contamination, each assay area was set up with three separate folding tables: (1) sample heat-inactivation and preparation, (2) preparation of RT-LAMP reagents and assay set-up, and (3) RT-LAMP incubation and imaging. Individuals responsible for sample inactivation and performing assays wore appropriate personal protective equipment (PPE) including N95 face masks, face shields or safety glasses, disposable lab coats, and double gloves. In anticipation of wet and cold fall weather, by September 2020, assay workspaces were transitioned to biosafety hoods in a vacant indoor laboratory space for several POC testing locations. In October 2020, we received IRB approval for obtaining consent for repeat SARS-CoV-2 testing. This allowed us to transition away from consenting participants at each testing time point and instead allowed each enrolled participant to consent once regardless of the number of times they supplied a sample. Following reports that SARS-CoV-2 RNA is stable in saliva at room temperature for prolonged periods³⁶, we also transitioned away from in-person sample collection at some of the testing sites and instead distributed self-collection take-home kits for drop off at designated locations for same day processing.

Sample collection and preparation

We obtained approval from the University of Wisconsin-Madison Institutional Review Board (#2020-0855 and #2020-1142). Participants were advised to avoid eating, or drinking anything except for water, for 30 minutes prior to providing a sample. After providing informed consent, volunteers self-collected at least 50 µl of saliva in a 1.5 ml “safe-lock” microcentrifuge tube using a 1000 µl unfiltered pipette tip to funnel the specimen into the tube. Each volunteer disinfected the outside of the tube with a pre-moistened disinfectant wipe. Samples collected in-person were typically processed within 3 hours of

collection through our RT-LAMP mobile testing workflow, while samples collected using take-home kits were typically processed within 30 hours (Figure 1). Samples were first incubated in a heat block at 65°C for 30 minutes to inactivate SARS-CoV-2³⁷ and then incubated in another preset heat block at 98°C for 3 minutes to improve nucleic acid detection and inactivate salivary enzymes³⁸. The inactivated saliva was then centrifuged for 2 minutes in a benchtop microcentrifuge. Fifty microliters of the saliva supernatant were then added to 50 µl of 1x phosphate buffered saline, pH 7.4 (1x PBS).

RT-LAMP reactions

Three microliters of the saliva/PBS mixture for each sample was added in duplicate to 17 µl of a colorimetric RT-LAMP reaction mix containing WarmStart colorimetric LAMP mastermix (NEB, catalogue# M1800), water, and a set of six SARS-CoV-2-specific RT-LAMP primers designed against the N gene³⁸. The SARS-CoV-2 RT-LAMP primer set was previously designed by Broughton et al. and is currently used in an FDA emergency use authorized (EUA) COVID-19 test by Color Genomics (Table 1)^{39, 40}. Reactions were incubated for 30 minutes at 65°C. A smartphone or tablet was used to record images of each reaction before (time = 0) and after the incubation period (time = 30). A color change from pink/orange to yellow in at least 1 of 2 replicates was scored relative to gamma-irradiated SARS-CoV-2 (irSARS-CoV-2, BEI Resources, Manassas, VA) that was directly added to RT-LAMP reactions as a positive control in each batch of reactions at concentrations ranging from 220-3,333 copies/µl (2.2×10^5 - 3.33×10^6 copies/ml). irSARS-CoV-2 was diluted and aliquoted as ready-to-run positive control standards and stored at -80°C. On the day of testing, the positive controls were removed from the freezer and stored on ice at POC sites. Individuals whose samples were recorded as potentially positive for SARS-CoV-2 by RT-LAMP were contacted by an infectious disease clinician in accordance with the IRB protocol and urged to obtain a clinical diagnostic test to confirm findings and self-isolate in accordance with public health recommendations.

Limit of detection (LOD) estimation using contrived saliva samples

To estimate the limit of detection of the RT-LAMP assay, contrived positive saliva samples were

163 prepared by adding irSARS-CoV-2 diluted from 1×10^4 - 10 copies/ μ l (1×10^7 - 1×10^4 copies/ml) or from
 164 5×10^4 - 50 copies/ μ l (5×10^7 - 5×10^4 copies/ml) directly into unaltered saliva collected from a total of 25
 165 SARS-CoV-2-negative individuals. Dilutions were based on two independent, in-house qRT-PCR
 166 experiments showing that the ir-SARS-CoV-2 stock concentration ranged from 7.89×10^6 - 8.23×10^6
 167 copies/ μ l (7.89×10^9 - 8.23×10^9 copies/ml). In two RT-LAMP experiments, four serial dilutions of irSARS-
 168 CoV-2 were prepared for each saliva sample in duplicate. RT-LAMP reactions were set up as described
 169 previously. Negative controls consisting of 1x PBS and positive controls consisting of 1×10^4 copies/ μ l
 170 (1×10^7 copies/ml) irSARS-CoV-2 in water were also prepared in duplicate. Reactions were called
 171 positive if a color change from pre-amplification to post-amplification occurred in at least 1 of 2
 172 replicates that was consistent with that of the positive controls.

173

174 Limit of detection (LOD) estimation using clinical samples

175 De-identified discard saliva samples from 38 SARS-CoV-2-positive patients were provided by the
 176 University of Wisconsin Hospitals and Clinics (UWHC) for evaluation of RT-LAMP performance with
 177 known positive saliva samples. Clinical saliva samples were originally collected and stored at 4°C for up
 178 to 4 weeks prior to assessment by RT-LAMP. Additional 10-fold and 100-fold dilutions were prepared
 179 for 13 of the samples in saliva collected from a negative volunteer. Clinical samples and dilutions were
 180 prepared as described previously except that 20-50 μ l of heat-inactivated sample, dependent on total
 181 sample volume, was added to an equal volume of 1x PBS in a clean 1.5 ml screw-top tube and pipetted
 182 gently to mix. For each sample, 3 μ l was then added to duplicate colorimetric RT-LAMP reactions.
 183 Negative and positive control reactions (described previously) were also prepared in duplicate except
 184 that saliva collected from a negative volunteer was used as the negative control for these reactions.
 185 RT-LAMP reactions were prepared and images collected as described previously.

186

187 Quantitative RT-PCR

188 POC samples

We measured vRNA concentration using sensitive qRT-PCR in a subset of the inactivated saliva samples described above after initial evaluation using RT-LAMP. Saliva samples that were negative for SARS-CoV-2 by RT-LAMP were pooled into groups of 6 or fewer for qRT-PCR to balance cost effectiveness with reasonable estimated detection sensitivity. Ten additional, individual RT-LAMP-negative samples were submitted as negative controls alongside samples identified as positive by RT-LAMP. Saliva samples that were identified as positive for SARS-CoV-2 by RT-LAMP were tested by qRT-PCR individually to estimate our POC LOD. RNA was isolated from up to 150 µl saliva and combined with an equivalent volume of nuclease-free water using the Viral Total Nucleic Acid kit for the Maxwell RSC instrument (Promega, Madison, WI) following the manufacturer's instructions. Viral load quantification was performed using a sensitive qRT-PCR assay developed by the CDC to detect SARS-CoV-2 (specifically the N1 assay) and commercially available from IDT (Coralville, IA). The assay was run on a LightCycler 96 or LC480 instrument (Roche, Indianapolis, IN) using the Taqman Fast Virus 1-step Master Mix enzyme (Thermo Fisher, Waltham, MA). The limit of detection of this assay is estimated to be 0.2 genome equivalents/µl (200 genome equivalents/ml) saliva. To determine the vRNA load, samples were interpolated onto a standard curve consisting of serial 10-fold dilutions of *in vitro* transcribed SARS-CoV-2 N gene RNA kindly provided by Nathan Grubaugh (Yale University) and described by Dudley et al.³⁵.

Clinical samples

qRT-PCR was performed using the conditions described above for each of the 38 SARS-CoV-2 positive saliva samples individually; however, sample volume limitations required that for some samples, only 100 µl saliva was combined with 100 µl of nuclease-free water prior to RNA isolation. In addition, sample UWHC3 contained a lower volume than the remaining 37 samples so 50 µl saliva was combined with 50 µl nuclease-free water and used for RNA isolation as described previously. Viral loads in copies per microliter and corresponding cycle threshold numbers (Ct) are reported in Table 2.

Results

216 LOD estimation using contrived saliva samples

217 We assessed the LOD for minimally processed saliva samples collected from 25 volunteers over two
 218 RT-LAMP experiments using irSARS-CoV-2 spiked into negative saliva samples (Figure 2A and 2B). In
 219 our first experiment (S1-S3), we detected irSARS-CoV-2 in at least 1 of 2 replicates at 1×10^2 copies/ μ l
 220 (1×10^5 copies/ml) in all 3 samples (Figure 2A). In our second experiment (S4-S25), we detected
 221 irSARS-CoV-2 by RT-LAMP in 2/2 replicates at 5×10^4 copies/ μ l (5×10^7 copies/ml) for 95% of samples,
 222 at 5×10^3 copies/ μ l (5×10^6 copies/ml) for 62% of samples, and at 500 copies/ μ l (5×10^5 copies/ml) for 10%
 223 of samples. When we included samples called positive in at least 1 of 2 replicates (see Methods), the
 224 percentage of contrived samples positive by RT-LAMP at each of the aforementioned dilutions were
 225 100%, 90%, and 33.3% respectively (Figure 2B). One sample was omitted from the analysis because it
 226 turned yellow before the RT-LAMP reaction incubation began and was therefore uninterpretable.
 227 Because in POC testing we defined a positive RT-LAMP result as an observed post-incubation color
 228 change to yellow in at least 1 replicate, these results suggested that our 90% LOD is between 1×10^2
 229 and 5×10^3 copies/ μ l (1×10^5 - 5×10^6 copies/ml).

230

231 LOD estimation using clinical samples

232 To assess the performance of SARS-CoV-2 RT-LAMP in known SARS-CoV-2 positive saliva samples
 233 as opposed to contrived positive samples, we acquired deidentified, discarded saliva samples collected
 234 from 38 patients with laboratory confirmed SARS-CoV-2 from UWHC. Nineteen of 38 undiluted saliva
 235 samples were positive for SARS-CoV-2 in 2/2 replicates by RT-LAMP (Figure 3; Table 2). Two
 236 additional samples were positive in 1 of 2 replicates. Quantitative RT-PCR data showed that the viral
 237 RNA (vRNA) loads of the positive samples ranged from 131 copies/ μ l to 5.7×10^4 copies/ μ l (1.31×10^5 -
 238 5.71×10^7 copies/ml) which was consistent with our LOD range for contrived samples (Table 3).
 239 Furthermore, for the 13 samples diluted 10-fold and 100-fold, detection decreased with increasing
 240 dilution factor (Table 4).

241

242 POC SARS-CoV-2 RT-LAMP testing

From July 16 to November 19, 2020, SARS-CoV-2 RT-LAMP was used to test a total of 4,704 samples collected from 5 locations. Participants were enrolled into the study regardless of their SARS-CoV-2 symptom status on the day of testing. Seventy-one percent of the samples were obtained from individuals at two research facilities, 11% from two K-12 schools, and 18% from an athletics program (Supplemental Table 1). A total of 21 samples were identified as positive for SARS-CoV-2 by RT-LAMP based on a colorimetric change from pink/orange to yellow in at least 1 of 2 sample replicates. Similar to our experience with our contrived LOD samples, about 0.40% (19/4,704) of samples collected during POC testing exhibited a color change to yellow prior to RT-LAMP assay amplification and were therefore uninterpretable. Follow up qRT-PCR testing was conducted on each sample that appeared positive after the 30 minute amplification reaction throughout the study to determine vRNA load. Twelve of the 21 samples called positive in RT-LAMP had detectable SARS-CoV-2 RNA by qRT-PCR. Viral RNA loads of these samples ranged from 8.58 copies/ μ l to 3.62×10^5 copies/ μ l (8.58×10^3 copies/ml- 3.62×10^8 copies/ml) with a median of 504.5 copies/ μ l (5.04×10^5 copies/ml) (Table 4). Eight of the saliva samples identified as positive by RT-LAMP were negative by qRT-PCR, suggesting that they were false-positive RT-LAMP results. One RT-LAMP-positive sample was not tested by qRT-PCR because the participant did not consent to additional molecular testing. For volunteers who consented to additional research testing from July 16 to September 17, qRT-PCR testing was conducted for pools of 6 or fewer for all residual, heat-inactivated samples that appeared unambiguously negative by RT-LAMP. A total of 421 RT-LAMP-negative pools (2,493 samples) were tested to estimate the number of SARS-CoV-2-positive samples missed by RT-LAMP. Quantitative RT-PCR detected SARS-CoV-2 nucleic acids in 5 pools of RT-LAMP-negative samples. Four out of five of the positive pools contained levels of SARS-CoV-2 that were below the estimated LOD range for RT-LAMP using crude samples with vRNA load estimates of 0.236, 0.444, 0.460, 37.5, and 142 copies/ μ l (236, 444, 460, 3.75×10^4 , and 1.42×10^5 copies/ml). Taken together, the low prevalence of SARS-CoV-2 in our volunteer testing population (0.36%, including RT-LAMP-negative, qRT-PCR-positive pools) and the low vRNA load of pools positive by follow-up qRT-PCR, suggest that these 5 pools likely contained only a single positive sample each and suggests a false-negative rate of 0.02% (5/2,493) (Table 4).

270

271 Discussion

272 Strategic surveillance testing of asymptomatic individuals has been suggested as an important
 273 mitigation strategy for places at high risk for close contact, indoor SARS-CoV-2 transmission: schools,
 274 workplaces, places of worship, and prisons, among others. Decentralized, mobile RT-LAMP-based
 275 POC testing workflows can provide same-day results which can enable people with potential SARS-
 276 CoV-2 infections to quickly self-isolate and then obtain confirmatory diagnostic testing. The low per-test
 277 cost (approximately \$7 per sample tested in duplicate) allows for repeated testing to identify incident
 278 infections and reduce the duration of a potentially infected individual's exposure to others. While RT-
 279 LAMP is not as sensitive as diagnostic qRT-PCR tests in laboratory testing, qRT-PCR tests require
 280 centralized labs, which in turn leads to lengthy turnaround times. Over a period of 18 weeks, we
 281 performed 4,704 SARS-CoV-2 tests across 5 sites using a simple, saliva-based, direct RT-LAMP
 282 assay. This work demonstrates the scalability of decentralized, mobile RT-LAMP-based testing and
 283 addresses a key knowledge gap of how POC RT-LAMP testing performs outside of well-equipped
 284 molecular biology laboratories.

285

286 Our initial experiments using direct RT-LAMP with contrived saliva samples from a total of 25 donors
 287 demonstrated a LOD that ranged from 1×10^2 copies/ μ l (100% in at least 1 replicate for S1-S3) to 5×10^3
 288 copies/ μ l (90% in at least one replicate for S4-S25). Taken together, these data suggest that the actual
 289 LOD for RT-LAMP without RNA isolation may be dependent on the individual sample due to
 290 heterogeneity of saliva pH and composition^{41–43}. Overall, the RT-LAMP results for 38 clinical saliva
 291 samples obtained from SARS-CoV-2-positive individuals at the UWHC, were consistent with those for
 292 the contrived samples. We recognize that more clinical samples are required for a comprehensive
 293 clinical validation, but the LOD observed in clinical samples is further supported by the low vRNA loads
 294 obtained from qRT-PCR-confirmed SARS-CoV-2-positive samples identified in our volunteer population
 295 (Table 4). The performance of our RT-LAMP POC testing workflow demonstrates that inexpensive,
 296 mobile testing can be successfully performed outdoors or in other non-traditional laboratory settings to

297 identify SARS-CoV-2-positive individuals regardless of whether or not symptoms are present. Our
 298 observed SARS-CoV-2 RT-LAMP positivity rate was 0.25% (12/4,704) for samples confirmed by follow-
 299 up qRT-PCR. Interestingly, the positivity rate of 0.25% in our volunteer population was lower than
 300 expected given the disease activity in our region during this period of time was listed as “critically high”,
 301 particularly between September 1 and November 19, 2020 when the county had a 5.42% positivity rate
 302 (19,031 positive tests out of 350,722)^{44, 45}. The low positivity rate in our volunteer population may be
 303 partly explained by the fact that 71% of tested saliva specimens came from two research facilities
 304 where mask wearing and physical distancing guidelines were implemented early in the pandemic and
 305 followed relatively stringently (Supplemental Table 1). Volunteers for nonsymptomatic research testing
 306 might also have a different risk profile from the overall population.

307
 308 Potential drawbacks of colorimetric RT-LAMP-based surveillance for SARS-CoV-2 as described here
 309 include the fact that minimally-processed saliva can result in variable reaction color change without the
 310 presence of the target RNA. However, modifications of RT-LAMP-based SARS-CoV-2 assays to
 311 reduce saliva sample variability, improve result ambiguity, and increase throughput have recently been
 312 reported elsewhere and may improve the implementation of RT-LAMP-based assays for POC use^{46–50}.
 313 In addition, we relied on a manual RT-LAMP format during POC testing. Reading assays “by eye”
 314 inevitably results in a somewhat subjective determination of positives. Reducing false-positive results in
 315 our POC volunteer populations required consistent use of duplicate reactions for each individual, which
 316 reduced assay throughput and increased the per-sample cost. Furthermore, the testing landscape
 317 changed dramatically during the months we performed RT-LAMP testing. The first non-instrumented
 318 antigen test, the Abbott BinaxNOW COVID-19 Ag CARD, received FDA EUA approval in the United
 319 States on August 26, 2020⁵¹. While the sensitivity of RT-LAMP is broadly comparable to the Abbott
 320 BinaxNOW antigen test (reported as 1.6×10^4 - 4.3×10^4 vRNA copies; Ct 30.3-28.8), because the former
 321 is technically straightforward and can be used as a SARS-CoV-2 diagnostic at testing sites operating
 322 under a Clinical Laboratory Improvement Amendments (CLIA) waiver, it is likely a better choice for
 323 rapid turnaround, on-site testing in most circumstances⁵². However, even with the existence of antigen

tests, RT-LAMP surveillance programs still have a place as part of a comprehensive SARS-CoV-2 risk mitigation strategy, especially in areas where access to antigen tests is limited.

There are advantages to continuing saliva-based RT-LAMP surveillance testing. Importantly, the supply of diagnostic antigen tests remains tightly constrained, and in the United States, these tests are available only through government contracts. Widespread testing of individuals without symptoms with such a scarce resource may not be a wise use of these limited tests. Furthermore, recent studies have shown that antigen test performance may differ between asymptomatic and symptomatic populations. Compared to qRT-PCR, the sensitivity of FDA-approved antigen tests, BinaxNOW and the Quidel Sofia SARS Antigen Fluorescent Immunoassay, were 35% and 41% in asymptomatic individuals and 64% and 80% in symptomatic individuals, respectively^{53, 54}. BinaxNOW is currently only approved for use in symptomatic individuals, within 7 days of symptom onset, and samples are required to be tested within an hour of collection⁵⁵. In contrast, RT-LAMP reagents do not require a government contract and can be acquired readily from commercial and non-commercial sources, and they can also be used more flexibly for surveillance purposes because RT-LAMP is not limited to use in symptomatic individuals⁵⁶. Additionally, user acceptance of testing may also favor saliva-based RT-LAMP as it is less invasive than nasal swab-based tests. While an individual BinaxNOW test is rapid, performing several tests during a single day could cumulatively take as long as processing a batch of tests by RT-LAMP. For these reasons, RT-LAMP may still be the preferred testing method to incorporate into a local program. In Madison, WI, two local schools have implemented RT-LAMP surveillance programs modeled on the program described here. Implementation of each program required approximately 50 hours of hands-on training by our group. School staff were trained in adherence to regulations pertaining to non-diagnostic testing and to competently perform RT-LAMP assays. Each school also needed time and resources to acquire the modest lab infrastructure necessary to perform RT-LAMP. In addition, a larger saliva-based RT-LAMP surveillance program has been successfully implemented in school districts in the greater Chicago suburbs^{57, 58}.

351 A looming question for both RT-LAMP and antigen testing programs is whether the real-world
 352 effectiveness of frequently testing individuals without symptoms mirrors the theoretical benefits. Several
 353 important considerations that we factored into the design of RT-LAMP testing remain true:
 354 nonsymptomatic individuals account for up to 59% of all transmission (24% asymptomatic and 35%
 355 presymptomatic); low-sensitivity tests are able to effectively identify those with high levels of virus
 356 shedding, and individuals with high viral loads are likely to be responsible for a significant fraction of
 357 onward community transmission; and the duration of peak infectiousness is short, so lengthy lags in
 358 reporting test results could miss a critical window of high transmissibility^{10, 59}. Conversely, high-quality,
 359 exceptionally well-resourced testing programs such as those at the White House and among
 360 intercollegiate athletic programs have failed to stop outbreaks⁶⁰. The latter deserves special note:
 361 outbreaks in these programs occurred in spite of 100% adherence to daily testing. Data from daily
 362 sampling of individuals with incident SARS-CoV-2 infection suggests that the mean duration of time
 363 from infection to peak viral shedding is approximately three days, but some individuals potentially reach
 364 peak viral shedding in under one day⁶¹. The potential for an extremely rapid increase in viral load,
 365 which likely parallels shedding of infectious virus, means that in some cases, even daily testing might
 366 be insufficient to protect a community from someone who is newly infected.

367
 368 Perhaps more importantly, the benefit of frequent testing of individuals without symptoms with RT-
 369 LAMP or other assays may be substantially undermined by risk disinhibition. When people are tested
 370 frequently, they may both underestimate their own risk of becoming infected in the interval between
 371 tests and overestimate the possibility that their similarly tested contacts are uninfected; anecdotal
 372 evidence of this phenomenon is perhaps most vividly seen in the September 26, 2020 White House
 373 Rose Garden reception for Justice Amy Coney Barrett, in which many attendees were photographed
 374 not wearing masks nor following guidelines for physical distancing⁶². If infections among people without
 375 symptoms are rare (~0.4% of tests in this study, when combining RT-LAMP and pooled qRT-PCR
 376 positives), but 10% of the tested population views testing as license for increased risk-taking, is
 377 frequent testing of symptomless people a net positive? Appropriate messaging to the community is

essential with any testing program to ensure the population understands the meaning of a test result. Such issues will require an optimization of messaging to mitigate the impact of risk disinhibition to the extent possible.

Ultimately, this study provides proof of concept and guidance for how decentralized rapid testing could be implemented in a mobile testing scenario, which may be especially useful in resource-limited settings. Despite the caveats presented above, we identified 12 SARS-CoV-2-positive individuals and likely prevented onward transmission from those individuals who otherwise would not know they were positive. Rapid tests, although less sensitive than qRT-PCR, have shorter turnaround times and could bridge the gap between SARS-CoV-2 surveillance and diagnostic testing. POC testing can be effective for identifying asymptomatic individuals but must be used in conjunction with appropriate messaging and other mitigation strategies to effectively reduce SARS-CoV-2 transmission.

Acknowledgments

This work was made possible by financial support through NIH Rapid Acceleration of Diagnostics (3 U54 EB027690-02S1). Additional funding was provided in part by the office of the director, National Institutes of Health, under award number P51OD011106 to the Wisconsin National Primate Research Center (WNPRC), University of Wisconsin-Madison. This research was conducted in part at a facility constructed with support from Research Facilities Improvement Program grant numbers RR15459-01 and RR020141-01. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health. Additional funding was provided by the Wisconsin Alumni Research Foundation (WARF) COVID-19 Challenge. A.S.H. and C.M.C. have been supported by the National Institutes of Health National Research Service Award T32 AI007414. We are grateful for the assistance of both the University of Wisconsin Institutional Biosafety Committee and the Health Sciences Institutional Review Board at University of Wisconsin-Madison. We also acknowledge Christopher E. Mason, PhD Cornell-Weill Medical School and Alison Kriegel, PhD Medical College of Wisconsin as well as public employees from Racine, WI in their partnership to this project. We would

like to thank Abigail Johnson, Abby Weaver, Abdel Daoud, Allison Eierman, Ben Boerigter, Clarissa Tjoanda, Julia Pulokas, Julie Chen, Ryan Anderson, Will Vuyk, Jenny Lee, Max Bobholz, Sam Havlicek, Hunter Ries, Nicole Minerva, Emma Boehm, Elizabeth Brown, and Jayden Lee for their help preparing and organizing supplies for POC testing. David Beebe, Nate Grubaugh, and Kristian Andersen provided useful technical discussions. We thank Eli O'Connor for assistance with POC label generation and template preparation. We are grateful to the study volunteers and organizations that allowed us to evaluate this mobile testing strategy.

Author Contributions

CMN, MDR, RWW, DMD, CGS, DHO, SLO contributed to assay development and optimization. DMD, MTM, RWW, CMN, MRS, AMW, MIB, KNF, MDR, LAH, OEH, RVM, CMC, SLO, MRR, TCF, TMP, EDS, LMS, EKN contributed to point of care testing and PCR confirmation. CMN, MDR, DMD, DHO contributed to data analysis, interpretation, and writing. JAK, DHO, SLO, HEB, TCF, MTM, AKH, LAH, CMC, KLH, CBB, KNF contributed to logistics and organization of point of care testing. CBB, KLH contributed to obtaining IRB and worked closely with the institutional biosafety committee on other regulatory responsibilities. MAA, ASH, WMR contributed to providing residual SARS-CoV-2 positive saliva samples and sample information from the University of Wisconsin Hospitals and Clinics. All authors contributed to editing the manuscript.

Regulatory oversight

This work was performed under approved UW-Madison Health Sciences IRB #2020-0855 and #2020-1142.

Figure legends

Figure 1: Point-of-care RT-LAMP SARS-CoV-2 testing workflow. Steps 1-5. Saliva sample preparation. **Steps 6-7.** RT-LAMP reagent preparation. **Steps 8-10.** RT-LAMP reactions and results interpretation. A reaction color change from pink/orange to yellow after 30 minutes in at least 1 of 2 sample replicates was scored as positive. Figure was created using BioRender.com.

Figure 2: Detection of SARS-CoV-2 in contrived saliva samples by direct RT-LAMP. A. Initial limit of detection (LOD) assessment with contrived saliva samples from 3 volunteers (S1, S2, S3). RT-LAMP reactions determined to be negative are pink and those determined to be positive are yellow. Quantitative RT-PCR vRNA loads are presented as copies/μl above the replicates for each sample. **B.** Bar graph showing an expanded assessment of RT-LAMP LOD for 22 additional contrived saliva samples (S4-S25). Gamma-irradiated SARS-CoV-2 (irSARS-CoV-2) vRNA load is shown as copies/μl on the x-axis, number of samples positive in 2 (black), 1 (dark gray), or 0 (light gray) replicates is shown on the y-axis.

689

690 **Figure 3: Detection of SARS-CoV-2 in 38 clinical saliva specimens by direct RT-LAMP.** The vRNA
691 load of each clinical sample is plotted on the x-axis relative to the in-house CDC N1 qRT-PCR assay
692 cycle threshold (Ct) on the y-axis. Black, dark gray, and light gray indicate 2, 1, and 0 positive replicates
693 respectively.

POC21	4.07×10^2

*Volunteer did not consent to follow-up testing.

Saliva preparation

1

Collect saliva in a 1.5 ml tube using 1000 µl pipette tip

2

Heat the saliva in heat block at 65°C for 30 minutes

3

Heat the saliva in heat block at 98°C for 3 minutes

4

Spin down tubes for 2 minutes in a microcentrifuge

5

Add 50 µl of saliva into 1.5ml tube with 50 µl PBS

RT-LAMP reagent preparation

6

Combine 10x primer stock, dH2O, and 2x WarmStart master mix

7

Aliquot 17 µl of the mix into PCR strip tubes

RT-LAMP reaction

8

Add 3 µl of diluted saliva into 17 µl of RT-LAMP mix in duplicate

9

Mix, spin down, and incubate in heat block at 65°C for 30 minutes

10

Read results:
pink = negative (-)
yellow = positive (+)

Results interpretation

negative (pink/pink)

positive (yellow/yellow)

positive (yellow/pink)

** all controls must be correct, otherwise test is invalid*
