Abstract:

Rationale

Pulmonary aspergillosis may complicate COVID-19 and contribute to excess mortality in intensive care unit (ICU) patients. The incidence is unclear because of discordant definitions across studies.

Objective

We sought to review the incidence, diagnosis, treatment, and outcomes of COVID-19-associated pulmonary aspergillosis (CAPA), and compare research definitions.

Methods

We systematically reviewed the literature for ICU cohort studies and case series including ≥ 3 patients with CAPA. We calculated pooled incidence. Patients with sufficient clinical details were reclassified according to 4 standardized definitions (Verweij, White, Koehler, and Bassetti).

Measurements

Correlations between definitions were assessed with Spearman's rank test. Associations between antifungals and outcome were assessed with Fisher's Exact test.

Main Results

38 studies (35 cohort studies and 3 case series) were included. Among 3,297 COVID-19 patients in ICU cohort studies, 313 were diagnosed with CAPA (pooled incidence 9.5%). 197 patients had patient-level data allowing reclassification. Definitions had limited correlation with one another ($\rho=0.330$ to 0.621 , $p < 0.001$). 38.6% of patients reported to have CAPA did not fulfill any research definitions. Patients were diagnosed after a median of 9 days (interquartile range 5-14) in ICUs. Tracheobronchitis occurred in 5.3% of patients examined with bronchoscopy. The

mortality rate (50.0%) was high, irrespective of antifungal use ($p=0.28$); this remained true even when the analysis was restricted to patients meeting standardized definitions for CAPA.

Conclusions

The reported incidence of CAPA is exaggerated by use of non-standard definitions. Further research should focus on identifying patients likely to benefit from antifungals.

Introduction:

Given the high morbidity and mortality associated with severe COVID-19 (1), it is imperative to rule out co-infections that may contribute to poor outcomes. In patients with severe COVID-19 requiring admission to the intensive care unit (ICU), pulmonary aspergillosis has been reported to be a relatively common and important complication contributing to increased mortality (2).

An association between viral respiratory tract infection and aspergillosis has been established in influenza: the incidence of influenza-associated pulmonary aspergillosis (IAPA) ranges from 7-30% within 3 days of ICU admission, and is associated with ~50% mortality (3,4). Similarly, aspergillosis has been reported to occur in up to a third of patients with critical COVID-19 (5–7). However, diagnosis and classification remains challenging.

Most reported cases of COVID-19 associated pulmonary aspergillosis (CAPA) have occurred in immunocompetent patients, and thus patients without histologic evidence of invasive fungal disease cannot meet the classic research definitions of the European Organization for Research and Treatment of Cancer - Mycoses Study Group Education and Research Consortium (EORTC-MSGERC) for probable aspergillosis, since these require the presence of immunocompromising host factors (8). Alternative research definitions for CAPA have been proposed, first modified from IAPA and subsequently refined given the rapid pace of data generation and knowledge synthesis (6,9–12).

A common limitation among these definitions is the characterization of CAPA by non-specific clinical and radiographic findings that are difficult to distinguish from COVID-19 alone.

Moreover, mycological findings (such as detection of *Aspergillus* in respiratory samples by culture, antigen detection, or PCR) cannot reliably distinguish between infection and colonization.

The lack of a validated research case definition may result in missed or mis-identified individual cases, thereby delaying appropriate antifungal therapy or resulting in unnecessary therapy, both of which may result in poor outcomes. We conducted a systematic review of case series and cohort studies assessing patients diagnosed with CAPA while in the ICU and report incidence, diagnostics, treatments and mortality.

Methods:

Protocol and Registration

The review protocol has been registered in PROSPERO International Prospective Register of Systematic Reviews, CRD42020204123. The review and reporting were conducted according to PRISMA guidelines.

Eligibility Criteria

We included cohort studies of patients with COVID-19 admitted to ICUs who were evaluated for pulmonary aspergillosis using fungal diagnostics (including direct microscopy, fungal culture, *Aspergillus* PCR, and/or galactomannan testing on respiratory tract specimens, and/or galactomannan or 1,3- β -D-glucan (BDG) testing in blood), and case series of ICU patients with CAPA. We excluded case reports with fewer than 3 patients.

Information Sources

We searched 3 electronic databases (PubMed, Embase and Web of Science) from database inception to March 13, 2021 irrespective of language to identify relevant studies. A separate search was conducted on medRxiv to search for studies posted ahead of peer-review. The search strategy was restricted to humans. Reference lists and cited bibliographies were also hand searched. Two reviewers assessed for study eligibility, selected studies and extracted data.

Where assessments were discordant and could not be settled by discussion between the reviewers, these were arbitrated by a third reviewer.

Search

The following search strategy was employed on PubMed from inception to March 13, 2021:

((("aspergillus"[All Fields]) OR ("aspergillosis"[All Fields]))) AND (((("sars cov2"[All Fields]) OR ("covid"[All Fields]) OR ("2019 ncov"[All Fields]) OR ("novel coronavirus"[All Fields])).

Similar search terms were used for the other databases.

Definitions

Several research definitions for CAPA have been proposed (Table 1). We analyzed these by extracting patient-level data and reclassifying patients according to 4 research definitions: an expert consensus definition for influenza-associated pulmonary aspergillosis (IAPA) adapted to COVID-19 (Verweij) (10), the CAPA definitions from Wales (White) (2), expert consensus definitions of the European Confederation of Medical Mycology (ECMM) and the International Society for Human and Animal Mycoses (ISHAM) for CAPA (Koehler) (11), and the EORTC-MSGERC Intensive Care Working Group definitions for invasive aspergillosis in ICU patients (Bassetti) (12).

Given that some data was not always explicitly stated, we made some assumptions. Firstly, all patients admitted to an ICU with COVID-19 were assumed to meet the clinical criteria for the definition proposed by White et al, i.e. had at least 1 of: refractory fever despite greater than 3 days antibiotics; recrudescence fever of ≥ 48 hours despite antibiotics; dyspnea; hemoptysis; pleural rub or chest pain; worsening respiratory function despite antibiotics and ventilatory support. Secondly, where radiological findings were not provided, abnormal imaging was assumed for critically ill patients with COVID-19. Thirdly, for the purpose of White et al

classification, radiographic abnormalities reported simply as being typical for COVID-19 were assumed to not be specific for pulmonary aspergillosis. On the other hand, because of the specific imaging requirements needed to meet the Bassetti et al classification, if radiographic results were not provided, these were considered unclassifiable. Immunocompromise was defined as per EORTC-MSGERC host factors for aspergillosis (8).

Risk of Bias Quality Assessment

A formal assessment for risk of bias was conducted using an adaptation of the Joanna Briggs Institute (JBI) cohort checklist tool for systematic reviews (13). These tools rated the quality of study by assessing for appropriate patient population, fungal diagnostics, definitions, outcomes and/or follow-up. Two reviewers assessed the quality of all included studies and discrepancies were arbitrated by a third reviewer.

Statistical Analysis

Descriptive data were reported for continuous outcomes. Dichotomous data and outcomes were reported as frequencies and proportions. The associations between antifungal therapy and mortality for patients with CAPA - defined as reported by authors and according to the 4 research definitions - were tested using Fisher's exact test. We excluded from the "as reported" analysis studies that used a non-standard definition for CAPA that specifically excluded those patients who improved without therapy. Diagnostic definitions were compared with Spearman's rank correlation (ρ), with $p=0.05$. Analyses were done using SPSS v26.0 (Armonk, New York, USA).

Role of the Funding Source

This study was unfunded.

Results:

Literature search

The search for publications identified 398 articles from PubMed (n=171), Embase (n=138), Web of Science (n=84), and grey literature and citations from general and systematic review papers (n=5). After removal of duplicates, 204 relevant studies were identified for title and abstract review. Eighty-three studies were eligible for full-text review, of which 38 met inclusion criteria, including 22 with patient-level data (Figure 1, Table 2). There were 35 cohort studies and 3 case series that were included. Individual patient details from studies meeting inclusion criteria are presented in Supplementary Table 1.

Risk of Bias Assessment Quality Assessment

All studies met overall inclusion criteria with differences noted in Table 2. Given the low quality of evidence (non-RCT studies), a GRADE analysis could not be performed.

Correlations between definitions

Four proposed definitions for CAPA were selected for analysis: (Verweij) (10), White (2), Koehler (11), Bassetti (12)), summarized in Table 1. From 22 studies, we identified 197 patients reported as having CAPA for whom patient level data was reported (Supplemental Table 1).

Among these, 71 (36.0%) met criteria of the Verweij et al definitions (4 proven tracheobronchitis, and 67 probable, without documented tracheobronchitis), 79 (40.1%) met the White et al definitions (4 proven tracheobronchitis, 77 putative), 97 (49.2%) met the Koehler et al definitions (4 proven tracheobronchitis, 63 probable, other pulmonary forms, and 30 possible, other pulmonary forms). One-hundred-and-forty-five patients could be classified according to the Bassetti et al definitions, and 52 were unclassifiable due to lack of radiographic details.

Among the 145 classifiable patients, 36 (24.8%) met the Bassetti et al criteria for CAPA (4 proven, 32 probable invasive aspergillosis). Seventy-six patients (38.6%) did not meet criteria for CAPA according to any definitions: 41 (20.8%) were classified as not meeting criteria for CAPA for all 4 definitions, and another 35 (17.8%) did not meet CAPA criteria for any of the Verweij, White, and Koehler definitions and were unclassifiable by Bassetti criteria. There was only modest agreement between any 2 definitions: the correlation coefficient, ρ , ranged between 0.330 and 0.621 (Table 2 and Figure 2).

Incidence of CAPA in the ICU

The incidence of CAPA in the ICU was calculated based on 3,297 patients across 34 cohort studies from 17 countries (Table 2). The incidence of CAPA in ICU patients ranged from 0-34.3% (Figure 3). Together, these studies reported 313 cases of CAPA, for a pooled incidence of 9.5% in ICU patients. Among 2,390 patients who were recorded as receiving invasive mechanical ventilation, there were 248 cases of CAPA reported, for a pooled incidence of 10.4%.

Among only cohort studies with patient-level details (18 studies comprising 1,665 ICU patients), the pooled incidence of CAPA – as reported – was 9.2%; upon reclassification to Verweij, White, Koehler, and Bassetti definitions, the pooled incidence was 3.6%, 4.1%, 5.2% and 1.6%, respectively (Table 4).

Patient Characteristics and Diagnosis

Twenty-two articles reporting 197 individuals with CAPA were included in the patient-level analysis (Supplementary Table 1). Demographic and clinical features of these cases are summarized in Table 5. The median age was 64 years (IQR 55 – 73) and 72.7% were male.

Immunocompromise status was present in 9 patients (4.6%). Eighty-one patients received immunomodulatory therapy: 67 patients (33.5%) received corticosteroids (in addition to 4 patients already on steroids at admission), and 29 (14.7%) received tocilizumab (15 patients received both). Additionally, patients were treated with the following therapies, alone or in combination: azithromycin (n=19), chloroquine or hydroxychloroquine (n=43), lopinavir/ritonavir or darunavir/cobicistat (n=24), ribavirin (n=1), interferon- β 1b (n=5), and remdesivir (n=5).

One-hundred-and-forty-nine patients (84.2%) received invasive mechanical ventilation, and 7 (3.6%) received extracorporeal membrane oxygenation (ECMO). The duration of invasive mechanical ventilation at CAPA diagnosis, known for 41 patients (27.5%), was a median of 6 days (IQR 3-10); duration of ICU admission at time of CAPA diagnosis, known for 73 patients (37.1%), was a median of 9 days (IQR 5-14).

Radiographic findings were described for 142 patients (72.1%). These were reported as showing non-specific abnormalities (n=13), infiltrates (n=24), consolidation (n=36), nodules (n=25), cavitations (n=17), and ground-glass opacities (n=28), or they were simply reported as being typical for COVID-19 (n=42).

Among patients reported to have CAPA, bronchoscopy was performed on 80 (40.6%), among whom just 4 (5.3%) – all from a single report – had tracheobronchial abnormalities, and in these patients tracheobronchial biopsies had histopathological evidence of invasive aspergillosis. At least 8 additional patients from cohort studies that lacked patient-level details had lesions on bronchoscopy (14,15). Bartoletti et al reported routine bronchoscopies on ICU admission, at 7 days, and with clinical deterioration (14). Thirty out of 108 patients were diagnosed with CAPA, including 6 (20%) with endobronchial lesions visualized on bronchoscopy.

Bronchial sampling was done on 123 CAPA patients, including bronchoscopic (n=80) and non-bronchoscopic lavage (NBL) (n=43). One-hundred sixteen patients had *Aspergillus* spp. cultured from a respiratory specimen. These included: *A. fumigatus* in 98 (84.5%), *A. flavus* in 4 (3.4%), *A. niger* in 2 (1.7%), *A. citronotterreus*, *A. lentulus*, *A. versicolor*, *Aspergillus* section *fumigati*, *A. terreus* and *A. calidoustus* in 1 (0.8%) each and 1 unspciated *Aspergillus* spp. Mixed infections were encountered in 5 (2.6%) additional patients: 3 with *A. fumigatus* and *A. flavus*, 1 with *A. fumigatus* with *A. versicolor* and 1 with *A. fumigatus*, *A. awamori* and *A. terreus*. These were cultured from BAL (n=45), bronchial aspirates (n=17), NBL (n=18), endotracheal aspirates (n=34), and sputum (n=2). PCR for *Aspergillus* species was done in 81 patients (41.1%) and was positive in 47 of these (58.0%). These included from BAL/BA in 9 patients, from NBL in 10 patients, from NBL and plasma in 2 patients, from NBL and serum in 2 patients, from bronchial aspirate in patients; from tracheal aspirate (TA) in 5 patients, from TA and BAL/BA in 6 patients. Four had PCR detection of *Aspergillus* species in serum, 1 from plasma and 1 from sputum.

Galactomannan was measured on bronchial fluid for 91 (46.2%) patients; 66 (72.5%) of these were positive (optical density index [ODI] ≥ 1) (Supplementary Table 1). Serum galactomannan was conducted on 81 (41.1%) patients, with 31 (38.3%) being positive (ODI ≥ 0.5). Serum BDG was conducted on 71 (36.0%) patients, of whom 36 (50.7%) had levels ≥ 80 pg/mL. Direct observation of branching hyphae was only reported in 3 patients (1.5%).

Treatment and Outcomes

Treatment and survival data was available for 182 patients. One-hundred-forty-one patients (77.5%) were treated with mould-active antifungals, including (alone or in combination) a mould-active azole (voriconazole, itraconazole, isavuconazole, or posaconazole; n=110),

amphotericin B (n=34), an echinocandin (n=22; used with a mould-active azole or amphotericin B in 20 cases, and alone in 2 cases); in 18 patients, the mould-active antifungal used was unclear. Forty-one (22.5%) patients did not receive mould-active antifungals.

In total, 91 patients survived (50.0%) and 91 patients died (50.0%). Among patients treated with mould-active antifungals, the survival rate was 53.0% (71/134) vs 41.4% (17/41) for patients who were not treated with mould-active antifungals ($p=0.28$). The lack of association between antifungal treatment and outcome persisted when the analysis was repeated for just those meeting each of the 4 CAPA definitions ($0.37 < p < 1.0$) (Table 6).

Discussion:

In this systematic review, we reviewed the incidence, diagnosis, management, and outcomes of CAPA, and compared research definitions. Overall, we found that the pooled incidence of CAPA, as reported, was 9.5% and varied widely between studies (0.0% to 34.3%), which may relate in part to surveillance practices and definitions used in individual reports.

Most patients with CAPA received invasive mechanical ventilation, although this association may be due to easier access to the lower respiratory tree for sampling and diagnosis. Most studies did not report bronchoscopy rates across the ICU cohort, so it is difficult to know if CAPA rates reflected discrepant use of this procedure in different centres. A small proportion of patients (5.6%) who had bronchoscopies were reported to have tracheobronchial abnormalities visualized. This is in contrast to IAPA, which has been observed to involve the tracheobronchial tree in up to half of all cases (10). While the presence of tracheobronchial disease should increase suspicion for CAPA, radiographic findings are insufficient to distinguish patients with CAPA from those with COVID-19 alone. In fact, a small minority of CAPA patients were

reported to have pulmonary nodules or cavitations, findings classically associated with invasive aspergillosis in immunocompromised hosts.

Aspergillus spp. were most commonly detected through bronchial fluid fungal culture and, to a lesser extent, galactomannan or PCR. A significant minority of patients had bronchial fluid sampling by NBL. The precise role for NBL in diagnosing CAPA is unknown: while it has often been favoured in the pandemic because of lower concern for aerosolization, a disadvantage is the inability to visualize signs of tracheobronchitis and obtain biopsies. In general, more proximal samples like TA and sputum are less specific and may overestimate CAPA, although one prospective study found reasonable rates of concordance of fungal culture between TA and BAL in CAPA (16). Some centres have incorporated screening protocols for CAPA with routine measurement of serum galactomannan and/or BDG (6,17,18). While galactomannan detection in serum is likely more specific for the diagnosis of invasive disease than in bronchial fluid (depending on cut-off values), the test lacks sensitivity. Among 106 CAPA patients with serum galactomannan, 34 were positive using the recommended cut-off of 0.5 ODI; only 18 had values ≥ 1.0 ODI.

Because of the novelty of COVID-19, various research definitions for CAPA have been used in the emerging literature. Research definitions for invasive aspergillosis in other settings (such as the EORTC-MSGERC definitions (8)) are poorly-suited because biopsies – required for antemortem diagnosis of proven invasive aspergillosis – are rarely pursued in ICU patients due to risk of complications in clinically tenuous individuals, and most patients with CAPA lack underlying host factors required for classification as probable invasive aspergillosis.

Consequently, most early studies used modifications of the *Asp*ICU score, adopted from studies of IAPA (4,9). Later, in a consensus definition for IAPA, Verweij et al proposed a parallel

definition for CAPA (10). White and colleagues proposed another definition (2). In December 2020, an expert panel convened by the ECMM and ISHAM proposed yet another research definition for the disease (11). Most recently, the EORTC-MSGERC Intensive Care Unit Working Group proposed definitions for invasive aspergillosis in ICU patients, including those with influenza and COVID-19 (12).

Our analysis of these definitions has identified several findings. Firstly, the incidence of CAPA may be overestimated in the literature because over a third of cases reported as CAPA did not fulfil any of these 4 standardized definitions (or were unclassifiable). For example, after pooling 21 ICU cohort studies that included patient-level data for 197 patients, the incidence of CAPA was 9.2% (as reported by authors), and this rate was considerably higher than when we reclassified these cases according to the 4 proposed standard definitions (between 1.6% and 5.2%).

Secondly, while there was overlap in the definitions, the correlation between any 2 was modest and so studies using discordant definitions may not be discussing the same patient populations. Thirdly, all definitions are hampered by lack of specificity since they all rely on clinical, radiographic, and mycological findings that may be difficult to distinguish from critically severe COVID-19.

In our study, the mortality rate of patients with CAPA was approximately 50% and was not clearly affected by antifungals. This observation remained true even when the analysis was repeated only in patients who met each of the 4 standardized research definitions for CAPA. A possible interpretation is that patients with CAPA might be diagnosed too late in their clinical course for antifungals to improve outcomes. Alternatively, for at least some patients, *Aspergillus* spp. in the airways reflects colonization and not invasive disease. A systematic review found that

autopsy-proven invasive mould disease is an uncommon finding in patients dying with COVID-19, occurring in < 2% of decedents reported in autopsy case series (19). Moreover, in some reported cases of probable CAPA, post-mortem examination failed to confirm the diagnosis (20). We observed a number of similarities and some contrasts with IAPA. Like with IAPA – and unlike invasive aspergillosis outside of ICU settings – most CAPA patients lacked pre-existing immunocompromising conditions. In contrast with IAPA, the timing of diagnosis of CAPA was late (occurring after a median 9 days after ICU admission), compared to after a median 2 days in IAPA (4). In addition, tracheobronchitis was rarely reported, noted in just 6% of cases in which bronchoscopy was done, in contrast to IAPA, in which it is reported to occur in one-third to one-half of affected patients (4,10).

Limitations

This study has some important limitations. Studies employed different surveillance methods and diagnostic tests to screen for and diagnose CAPA, and thus pooled analyses should be interpreted with caution. For example, studies that employed more aggressive surveillance – e.g. by routine bronchoscopy with fungal culture and galactomannan – would likely report higher rates of CAPA than studies in which fungal investigations were obtained only based on clinical suspicion, but conversely, may also over-represent those with *Aspergillus* spp. colonization. There was also inconsistent reporting related to clinical characteristics and diagnostics, both in patients reported to have CAPA and the rest of the ICU cohorts, limiting comparisons. For example, the use of corticosteroids and other immunomodulators were infrequently reported in CAPA and non-CAPA patients, precluding meaningful comparison. The degree to which these therapies may increase risk of CAPA is unclear (19). Finally, we did not formally assess risk of

bias, and it is possible that the design of some cohort studies resulted in bias towards over- or underdiagnosing CAPA.

Conclusions:

The reported incidence of CAPA in ICU patients with COVID-19 varies greatly by study, and may be related to different surveillance protocols and inconsistent definitions which may inflate the incidence compared to standard research definitions. Although several clinical research definitions have been advanced for the diagnosis of CAPA, agreement between these is imperfect, and none clearly distinguishes which patients are likely to benefit from antifungal therapy.

Contributions

RMK designed the literature search, created the figures, and wrote the first draft of the manuscript. RMK, TCD, BEK, and ISS screened and reviewed articles, and extracted and analyzed data. RMK, WIS, and ISS performed statistical analysis. ISS designed the study and was responsible for overall supervision. All authors critically reviewed and revised the manuscript and approved the final draft.

Declaration of Interests

ISS received personal fees from AVIR Pharma, outside the submitted work. TCD has received research grant funding from AVIR Pharma and clinical trial support from BioMérieux, outside the submitted work. All other authors declare no conflicts.

FIGURE LEGENDS:

Figure 1. PRISMA flowchart.

Figure 2. Venn diagram illustrating number of patients meeting each CAPA classification.

Ninety-three (47%) additional patients reported in the literature as having CAPA did not meet any of these definitions. Fifty-two patients were unclassifiable per Bassetti criteria due to lack of radiographic details.

Figure 3. Reported incidence of COVID-19-associated pulmonary aspergillosis in ICU cohort studies.

Supplementary Data Files:

Supplementary Table 1: Patient level data and reclassifications.

Table 1. Research definitions of COVID-19 associated pulmonary aspergillosis

Definition	Clinical and Host Factors	Radiologic Findings	Mycological Investigations	Ref
Verweij				(10)
Proven <i>Aspergillus</i> tracheobronchitis		Tracheobronchitis	Biopsy or brush specimen of airway plaque, pseudomembrane or ulcer showing hyphal elements AND <i>Aspergillus</i> growth on culture OR Positive <i>Aspergillus</i> PCR in tissue	

<p>Probable</p> <p><i>Aspergillus</i></p> <p>tracheobronchitis</p>		<p>Tracheobronchitis</p>	<p>Airway plaque, pseudomembrane or ulcer</p> <p>AND ≥ 1 of the following:</p> <ol style="list-style-type: none"> 1) Serum GM ≥ 0.5 ODI 2) BAL GM ≥ 1.0 ODI 3) Positive BAL culture 4) Positive TA culture 5) Positive sputum culture 6) Hyphae consistent with <i>Aspergillus</i>
<p>Proven, without documented</p> <p><i>Aspergillus</i></p> <p>tracheobronchitis</p>		<p>Without documented <i>Aspergillus</i> tracheobronchitis</p>	<p>Lung biopsy showing invasive fungal elements and <i>Aspergillus</i> growth on culture or positive <i>Aspergillus</i> PCR in tissue</p>

Probable, without documented <i>Aspergillus</i> tracheobronchitis		Pulmonary infiltrate OR Cavitating infiltrate (not attributed to another cause)	<p>In the case of pulmonary infiltrate, ≥ 1 of:</p> <ol style="list-style-type: none"> 1) Serum GM ≥ 0.5 ODI 2) BAL GM ≥ 1.0 ODI <p>In the case of cavitating infiltrate, ≥ 1 of:</p> <ol style="list-style-type: none"> 1) Positive sputum culture 2) Positive TA culture
White			(2)

Proven	<p>PCR-confirmed COVID-19 infection and 1 of:</p> <ol style="list-style-type: none"> 1) Refractory fever despite ≥ 3 days antibiotics 2) Recrudescence fever of at least 48 hours despite antibiotics 3) Dyspnea 4) Hemoptysis 5) Pleural rub or chest pain 6) Worsening respiratory function despite antibiotics and 	<p>New infiltrates on chest x-ray or chest CT when compared to admission, including progression of signs attributed to viral infection. Abbreviations: BAL: bronchoalveolar lavage; BDG: 1-3-β-D-glucan; CAPA: COVID-19 associated pulmonary aspergillosis; CT: computed tomography; ECMM-ISHAM: European Confederation of Medical Mycology-International Society for Human and Animal Mycoses; GM: galactomannan; HIV: human immunodeficiency virus HSCT: hematopoietic stem cell transplant; IA: invasive aspergillosis; IAPA: influenza-associated pulmonary aspergillosis; LFA: lateral flow assay; mTOR: mammalian target of rapamycin; NBL: non-bronchoscopic lavage; ODI: optical density index; PCR: polymerase chain reaction; SOT: solid organ transplant TNF: tumor necrosis factor

Table 2. Characteristics and findings of included studies.

Author	Country	Among ICU patients	Among intubated patients	Design	Patient selection for fungal investigations	Surveillance protocol: mycologic tests	Definition Used
		No. CAPA/ No. Total (%)	No. CAPA/ No. Total (%)				
Cohort Studies							
Alanio (5)	France	9 /27 (33.3%)	9/27 (33.3%)	Prospective cohort study	Successive mechanically vented patients with COVID-19.	On day 3 post-intubation: BAL culture, BAL/BA/serum qPCR (≥0.5 ODI), BAL/serum GM (≥0.8 ODI), serum BDG	Modified <i>Asp</i> ICU (non-immunocompromised) and Modified EORTC/MSGERC (if immunocompromised). Putative if BAL culture positive OR 2 of the following positive: qPCR in BAL/BA/serum, BA culture, BAL GM, serum GM, BDG
Brown (6)	UK	2 /62 (3.2%)	2/62 (3.2%)	Prospective cohort study	Successive mechanically vented patients with COVID-19.	Weekly serum BDG and GM (≥0.5 ODI); TA GM and culture at clinician discretion. If TA GM positive (≥1.0 ODI), TA qPCR	Modified <i>Asp</i> ICU
Dupont	France	19 /106	18/87	Retrospective	Clinician discretion	BAL/BA/TA direct	Modified <i>Asp</i> ICU;

(21)		(17.9%)	(20.7%)	cohort study		exam, serum/BAL GM (≥ 1.0 ODI), BAL/BA/TA culture	COVID-19 also considered a risk factor as per Koehler definition.
Helleberg (17)	Denmark	2 /27 (7.4%)	2/27 (7.4%)	Prospective cohort study	Successive patients on ECMO or mechanically ventilated for COVID-19 screened with TA fungal culture, serum GM. Other testing at clinician discretion	TA culture, TA/serum GM; BAL at clinician discretion	<i>AspICU</i>
Koehler (11)	Germany	5 /19 (26.3%)	5/19 (26.3%)	Retrospective cohort study	Clinician discretion	Serum GM (≥ 0.5 ODI), BAL or TA GM (≥ 0.5 ODI) fungal culture (BAL or TA), Fungal PCR (BAL or TA)	Modified <i>AspICU</i> plus positive GM from BAL or TA, or 2 consecutive positive serum samples
Lamoth (22)	Switzerland	3 /118 (2.5%)	3/80 (3.8%)	Prospective cohort study	Successive critically ill patients with COVID-19	Serum GM (≥ 0.5 ODI), BA/BAL culture, BA/BAL GM (≥ 1.0 ODI)	Modified Verweij: ≥ 2 positive BA cultures also considered for putative IPA
Nasir (23)	Pakistan	5 /23 (21.7%)	NA	Retrospective cohort study	Clinician discretion	BAL/TA/sputum culture, serum GM (≥ 0.5 ODI), BAL GM (≥ 1.0 ODI), BDG	Modified <i>AspICU</i>
Rutsaert (24)	Belgium	7/34 (20.6%)	7/20 (35.0%)	Prospective cohort study	Successive critically ill patients with COVID-19 screened with twice weekly serum GM; BAL GM and fungal	Serum GM (≥ 0.5 ODI) twice weekly; BAL GM (ODI cut-off not indicated), BAL culture, direct exam and culture, biopsy	<i>AspICU</i>

					culture when bronchoscopy done for any clinical indication	(when tracheobronchial lesions seen).	
Van Arkel (18)	Netherlands	6/31 (19.4%)	6/31 (19.4%)	Retrospective cohort study	Clinician discretion	BAL/TA/sputum culture, serum/BAL GM; Serum GM performed routinely, BAL performed if feasible	Verweij
Van Biesen (25)	Netherlands	9/42 (21.4%)	9/42 (21.4%)	Prospective cohort study	Successive mechanically vented patients with COVID-19.	NBL GM (≥ 1.0 ODI) and fungal culture on non-transparent fluid	Own: No host factor required, NBL used instead of BAL and patient had to have worsening clinical symptoms
White (2)	Wales	19/135 (14.1%)	15/122 (12.3%)	Prospective cohort study	Critically ill COVID-19 patients with refractory severe respiratory illness or deterioration of respiratory function 1 week post COVID diagnosis	Blood culture, BDG, BAL/NBL fungal culture, serum GM (≥ 0.5 ODI), BAL/NBL GM (≥ 1.0 ODI), PJP PCR, BAL/NBL/blood PCR	White, <i>Asp</i> ICU, Verweij
Lahmer (26)	Germany	11/32 (34.4%)	11/32 (34.4%)	Prospective cohort study	Mechanically ventilated patients with COVID-19 were screened for 28 days using a standardized study protocol	GM from NBL & serum; NBL for fungal culture on ICU admission and days 3, 7, and then every 3 days thereafter.	Modified <i>Asp</i> ICU

Bartoletti (14)	Italy	30/108 (27.8%)	30/108 (27.8%)	Prospective cohort study	Routine screening BAL on admission to ICU, at day 7 of invasive mechanical ventilation, and if clinical deterioration (defined as worsening of fever or increases in respiratory secretions or deterioration in respiratory status after a period of clinical stability)	Serum GM, BAL GM & fungal culture; if positive, BAL <i>Aspergillus</i> PCR	Verweij
Wang (15)	China	8/26 (30.8%)	4/15 (26.7%)	Retrospective cohort study	NA	NA	Modified EORTC-MSGERC
Ichai (27)	France	6/26 (23.1%)	NA	Cohort study	NA	NA	NA
Gangneux (28)	France	7/45 (15.6%)	7/45 (15.6%)	Prospective cohort study	Twice weekly testing of respiratory samples (NBL, TA, or BAL) in all intubated COVID-19 patients	<i>Aspergillus</i> spp. Detection by culture and PCR on respiratory samples (TA, NBL or BAL). Positive results followed up by serum GM, PCR, and anti- <i>Aspergillus</i> antibody	Modified <i>Asp</i> ICU additionally incorporating serum PCR, GM, anti- <i>Aspergillus</i> antibody
Sarrazyn (29)	Belgium	4/26 (15.4%)	NA	Retrospective cohort study	<i>Aspergillus</i> PCR and GM routinely done	Testing of NBL or TA with fungal culture,	Modification of Modified <i>Asp</i> ICU:

Garcia-Vidal (16)	Spain	3/146 (2.1%)	3/87 (3.4%)	Retrospective cohort study	on NBL (sent at clinician discretion); other tests at clinician discretion Clinician discretion	GM, <i>Aspergillus</i> PCR NA	‘Putative IPA’ : Aspergillus spp. in BAL culture; or at least 2 of: Aspergillus spp. in culture of NBL, GM in NBL/BAL (>1.0) or positive Aspergillus PCR in NBL/BAL Own: <i>Aspergillus</i> tracheobronchitis defined as isolation of <i>Aspergillus</i> species from endobronchial specimens of intubated patients with purulent secretions, as well as clinical validation from an investigator
Agrifolio (30)	Italy	2/139 (1.4%)	NA	Retrospective cohort study	NA	BAL fungal culture	NA
Van Grootveld (20)	Netherlands	11/63 (17.5%)	11/63 (17.5%)	Retrospective cohort study	Screening twice weekly (TA); Bronchoscopy for confirmation if feasible and clinically indicated	TA fungal culture and <i>Aspergillus</i> PCR; BAL fungal culture, GM, <i>Aspergillus</i> PCR	ECMM-ISHAM (Koehler)
Ripa (31)	Italy	10/86 (11.6%)	NA	Retrospective cohort study	Clinician discretion	Serum, NBL/BAL GM ; NBL/BAL culture	Modification of <i>Asp</i> ICU to include serum or BAL GM

Versyck (32)	France	2/54 (3.7%)	2/54 (3.7%)	Retrospective cohort study	Routine screening with serum tests in all ARDS patients; bronchoscopy if serum tests abnormal	Weekly BDG, serum GM (≥ 0.5 ODI); confirmatory BAL for direct microscopy, fungal culture, GM (≥ 0.8 ODI)	Modified <i>Asp</i> ICU
Rothe (33)	Germany	9/50 (18.0%)	NA	Retrospective cohort study	Clinician discretion	Standard hospital microbiological procedures.	None: Aspergillus isolated from respiratory sample
Maes (34)	UK	3/81 (3.7%)	3/81 (3.7%)	Retrospective cohort study	Clinician discretion	NA	Modified <i>Asp</i> ICU plus PCR
Dellièrre (35)	France	21/366 (5.7%)	21/246 (8.5%)	Retrospective cohort study	Clinician discretion	Respiratory specimen culture, <i>Aspergillus</i> PCR, BAL GM, serum/plasma GM, BDG, <i>Aspergillus</i> PCR	EORTC-MSGERC (Donnelly) and IAPA (Verweij)
Permpalung (36)	USA	39/396 (9.8%)	39/396 (9.8%)	Retrospective cohort study	Clinician discretion	BAL GM and culture; TA culture; serum GM, BDG	Own: “Probable CAPA” ≥ 1 of : new cavitory lung lesion(s) on chest CT without alternative explanation, positive GM on serum (≥ 0.5) or BAL (≥ 1.0), or <i>Aspergillus</i> cultured in BAL; and Possible CAPA: ≥ 1 of: BAL GM (0.5 – 1.0); serum BDG ≥ 80 pg/ml without alternative explanation; or

							<i>Aspergillus</i> cultured from TA
Segrelles-Calvo (37)	Spain	7/215 (3.3%)	NA	Retrospective cohort study	Patients in ICU or respiratory intermediate care unit had respiratory secretions or sputum collected every two weeks; unclear how patients selected for BAL/NBL	BAL GM (≥ 0.5 ODI); cultures	Modification of EORTC-MSG; host factors apparently not needed; imaging assessed based on classified according to the radiographic assessment of lung edema (RALE) score
Razazi (38)	France	7/90 (7.8%)	7/90 (7.8%)	Retrospective cohort study	NA	NA	Verweij, <i>AspICU</i> , Modified <i>AspICU</i>
Roman-Montes (39)	Mexico	14/144 (9.7%)	14/144 (9.7%)	Prospective cohort study	Clinician discretion based on suspicion of VAP or clinical worsening	TA fungal and bacterial culture, GM; serum GM (≥ 0.5 ODI)	Modified <i>AspICU</i>
Machado (40)	Spain	8/239 (3.3%)	8/239 (3.3%)	Prospective cohort study	Clinician discretion	GM (serum ≥ 0.5 ODI, BAL ≥ 1.0 ODI), serum BDG, respiratory sample fungal culture	Modified <i>AspICU</i> and EORTC-MSGERC
Meijer (41)	Netherlands	13/66 (19.7%)	13/66 (19.7%)	Prospective cohort study	NA	GM, BDG, <i>Aspergillus</i> PCR, fungal culture	Koehler
Sogaard (42)	Switzerland	2/41 (4.9%)	2/34 (5.9%)	Retrospective cohort study	NA	<i>Aspergillus</i> PCR, serum GM (cut-off not indicated), fungal culture	NA

Borman (43)	UK	13/61 (21.3%)	NA	Retrospective cohort study	Clinician discretion	Serum and respiratory samples subjected to BDG and GM, PCR on request. Microscopic examination, culture of BAL or TA	Modified <i>Asp</i> ICU
-----------------------	----	------------------	----	-------------------------------	----------------------	--	-------------------------

Fekkar (44)	France	6/145 (4.1%)	6/145 (4.1%)	Retrospective cohort study	Clinician discretion based on suspicion for VAP or clinical deterioration	Culture, GM (serum ≥0.5 ODI, respiratory sample ≥1.0 ODI), BDG and PCR	EORTC/MSG for immunocompromised; own definition for non- immunocompromised patients, who were classified as putative invasive pulmonary mold infection or false positive/colonization. All patients with ≥1 mycological test result (culture, GM, <i>Aspergillus</i> PCR, or BDG) were analyzed as potential cases. They were considered as false positive/colonization if: GM or PCR positive with further negative controls and/or mold culture in respiratory samples with further negative samples without clinical worsening; or clinical improvement without antifungals
-----------------------	--------	-----------------	-----------------	-------------------------------	--	---	---

Boyd (45)	Ireland	0/55 (0.0%)	0/55 (0.0%)	Retrospective cohort study	NA	BAL and serum GM	NA
Overall (for cohort studies)		313/ 3297 (9.5%)	248/2390 (10.4%)				
Case series							
Marr (46)	USA	20	20	Case series	Clinical discretion (as indicated for possible secondary infection, typically due to new fever or infiltrates)	NA	Own: Recovery of <i>Aspergillus</i> spp. from TA, sputum, BAL or positive serum or respiratory GM (≥ 1.0 ODI), BGD (≥ 80 pg/mL)
Mitika (47)	USA	4	4	Case series	Clinician discretion	Fungal cultures routinely performed on bronchoscopy specimens; other respiratory specimens as requested	<i>Asp</i> ICU
Benedetti (48)	Argentina	5	5	Case series	Clinician discretion	Fungal cultures of sputum, TA; GM in serum >0.5 ODI; GM in respiratory samples ≥ 1.0 , CT scan	Verweij

Note: Alanio et al not included in calculation of incidence because the same patients were captured in Delli $\square$ re et al. Brown et al and Fekkar et al not included in analysis of association between treatment and outcome in patients with CAPA (defined as reported) because improvement without antifungals was an exclusion criteria in their definitions.

Abbreviations: BA: bronchial aspirate; BAL: bronchoalveolar lavage; BDG: 1,3- β -D-glucan; CAPA: COVID-19 associated pulmonary aspergillosis; CT: computed tomography; BDG: 1-3- β -D-glucan; EORTC-MSG: European Organization for Research and Treatment of Cancer-Mycoses Study Group; GM: galactomannan; ODI: optical density index; NA: not available; NBL: non-bronchoscopic lavage; TA: tracheal aspirate; VAP: ventilator associated pneumonia

Table 3. Correlations between 4 different definitions of COVID-19 associated pulmonary aspergillosis

Spearman's rho (ρ)			Verweij	White	Koehler	Bassetti
	Verweij	ρ		.463	.615	.413
		N		197	197	145
	White	ρ	.463		.621	.356
		N	197		197	145
	Koehler	ρ	.615	.621		.330
		N	197	197		145
	Bassetti	ρ	.413	.356	.330	
		N	145	145	145	

All correlations are significant at the 0.01 level (2-tailed).

Table 4: Incidence of CAPA in ICU cohort studies as reported and after reclassification according to 4 research definitions

Study	Number ICU patients	Number of ICU patients with CAPA				
		as reported	per Verweij	per White	per Koehler	per Bassetti
Alanio	27	9 (33.3%)	7 (25.9%)	6 (22.2%)	8 (29.6%)	1 (11.1%)
Brown	62	2 (3.2%)	0 (0%)	0 (0%)	0 (0%)	1 (1.6%) ^a
Dupont	106	19 (17.9%)	11 (10.4%)	2 (1.9%)	17 (16.0%)	4 (3.8%)
Helleberg	27	2 (7.4%)	1 (3.7%)	1 (3.7%)	1 (3.7%)	0 (0%)
Koehler	19	5 (26.3%)	4 (21.1%)	4 (21.1%)	4 (21.1%)	5 (26.3%)
Lamoth	118	3 (2.5%)	1 (0.8%)	3 (2.5%)	3 (2.5%)	0 (0%)
Nasir	23	5 (21.7%)	0 (0%)	0 (0%)	0 (0%)	0 (0%)
Rutsaert	34	7 (20.6%)	6 (17.6%)	5 (14.7%)	6 (17.6%)	4 (11.8%) ^b

Van Arkel	31	6 (19.4%)	3 (9.7%)	1 (3.2%)	1 (3.2%)	0 (0%) ^c
Van Biesen	42	9 (21.4%)	0 (0%)	7 (16.7%)	7 (16.7%)	0 (0%)
White	135	25 (18.5%)	3 (2.2%)	19 (14.1%)	15 (11.1%)	5 (3.7%)
Van Grootveld	63	11 (17.5%)	10 (15.9%)	8 (12.7%)	9 (14.3%)	1 (1.6%)
Versyck	54	2 (3.7%)	2 (3.7%)	2 (3.7%)	2 (3.7%)	2 (3.7%)
Segrelles-Calvo	215	7 (3.3%)	0 (0%)	0 (0%)	0 (0%)	0 (0%)
Roman-Montes	144	14 (9.7%)	6 (4.2%)	5 (83.3%)	6 (4.2%)	0 (0%)
Machado	239	8 (3.3%)	3 (1.3%)	3 (1.3%)	3 (1.3%)	1 (0.4%) ^b
Fekkar	260	6 (2.3%)	0 (0%)	0 (0%)	0 (0%)	0 (0%) ^c
Meijer	66	13 (19.7%)	3 (4.5%)	3 (4.5%)	4 (6.1%)	2 (3.0%)

Pooled Total	1,665	153 (9.2%)	60 (3.6%)	69 (4.1%)	86 (5.2%)	26 (1.6%)
-----------------	-------	------------	-----------	-----------	-----------	-----------

Note: Only ICU cohort studies that included patient-level details allowing CAPA reclassification are included. Abbreviations: CAPA – COVID-19-associated pulmonary aspergillosis; ICU – intensive care unit. Footnotes: ^a1 patient was unclassifiable; ^b3 patients were unclassifiable; ^c6 unclassifiable;

Table 5. Demographic and clinical features reported for 197 patients reported to have CAPA for whom patient-level details are available

Characteristic	
Age, Median years (IQR)	64 (55 – 73) ^a
Sex, Males (%)	125/172 (72.7%)
Immune compromised*	9 (5%)
Systemic steroids	66 (33.5%)**
Tocilizumab	28 (14.2%)
Azithromycin	19 (9.6%)
Invasive mechanical ventilation	149 (84.2%)
ECMO	7 (3.6%)
Radiography	
Nodules	25***

Cavitations	17
Bronchoscopy	76/155 (38.6%)
Tracheobronchial abnormalities****	4/76 (5.3%)
Mould-active antifungals	141/182 (77.5%)
Deaths	91/182 (50.0%)
Timing of CAPA diagnosis, median days from ICU admission (IQR) ^b	9 (5 - 14) ^b
Timing of CAPA diagnosis, median days of mechanical ventilation before diagnosis (IQR)	6 (3-10) ^c

Data missing for: ^a25 patients, ^b124 patients, ^c108 patients

Notes: * Per European Organization for Research and Treatment of Cancer – Mycoses Study Group Education and Research Consortium consensus definitions for host factors; **plus 4 already on steroids; ***1 additional patient had nodules attributed to known pulmonary metastases.

Abbreviations: CAPA: COVID-19 associated pulmonary aspergillosis; ICU: intensive care unit; IQR: interquartile range; ECMO: extra-corporeal membrane oxygenation

Table 6. Comparison of antifungal treatment and survival across different COVID-19 associated pulmonary aspergillosis (CAPA) definitions

CAPA definition	Survived/Treated (%)	Survived/Not treated (%)	P-value
As reported (n=174)	71/134 (52.9%)	17/40 (41.4%)	0.28
Verweij (n=70)	25/54 (46.3%)	9/16 (56.3%)	0.57
White (n=77)	34/64 (53.1%)	5/13 (38.5%)	0.37
Koehler (n=96)	41/73 (56.2%)	12/23 (52.2%)	0.81
Koehler (proven/probable only) (n=66)	24/51 (47.1%)	8/15 (53.3%)	0.77
Bassetti (n=34)	17/30 (56.7%)	2/4 (50.0%)	1.0

Fisher's exact test with two-tailed P values.
