

Text S1:

Dependent variables used were:

- Month of COVID-19 admission, or, for question 1, month of symptom onset, as a discrete variable. April was used as the reference category; this is because the first month chronologically, March, was an outlier in many ways and comparisons with that month tended to give universally small p -values when compared to other months.
- Sex
- Final outcome (death or discharge)
- Age group (at admission), defined as 0-19, 20-39, 40-59, 60-69, 70-79, or 80+. The 40-59 age group was used as the reference category,
- For questions 2 to 5, either the time from symptom onset to hospital admission, or a variable indicating a nosocomial infection. This was binned as follows: nosocomial infection, 0-6 days, 7-13 days, and 14 days or greater. 0-6 days was the reference category.
- Country. In each analysis, countries with less than 200 patients represented were grouped by continent. Note that, due to differences in recruitment procedures between sites in the consortium, estimated regression coefficients for this variable should not be taken as representative of overall differences in clinical care between countries, nor of demographic differences.
- The four most common symptoms recorded at admission were cough, fatigue, fever, and shortness of breath. For question 1, the number of these that were reported at hospital admission was counted, giving a score from 0 to 4. Missing data on these was counted as

absence. It was excluded from questions 2 to 5 because it proved to be highly collinear with time from onset to admission (see Results).

- The presence or absence of three gastrointestinal symptoms - abdominal pain, diarrhoea, and vomiting - was also recorded on admission. The number of these was counted to give a score from 0 to 3, as above, and used in all analysis except 6.
- A wide variety of comorbidities were also recorded (see table S1). As these data were frequently not recorded, such that treating unknown values as missing would severely decrease the size of the dataset used in the regression analyses, we allowed these variables to take separate values of “Present”, “Absent” and “Unknown”. These were not used in analyses 1 or 6.

Figure S1: Proportion of patients entering ICU (a) and time from COVID-19 admission to ICU admission (b) over time. Each line is the proportion (a) or mean value (b) amongst all patients (black, dotted) or patients in each age group (coloured).

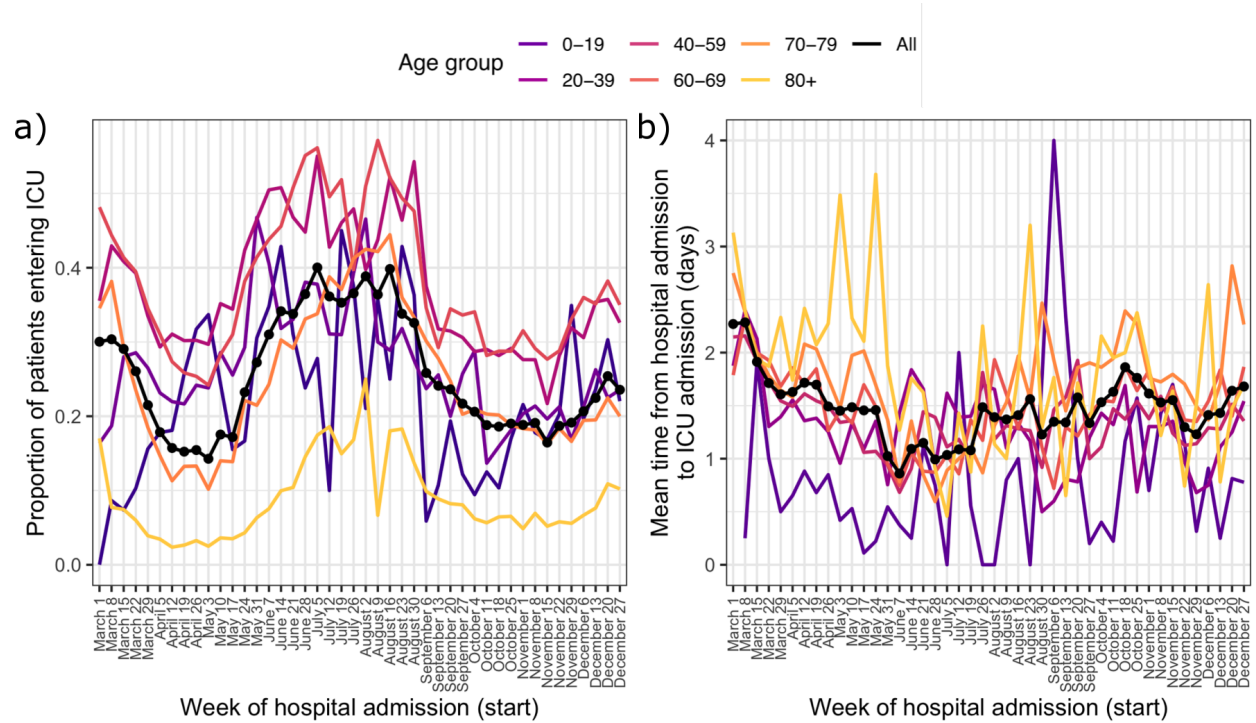

Figure S2: Extended version of figure 2, displaying Sankey plots for the patient journey for patients admitted in every month from March to December, subdivided by age group. Bars are presented for the day of admission (A), three and seven days later (A+3 and A+7), and the day after final outcome (O+1). Bars are presented for the day of admission (A), three and seven days later (A+3 and A+7), and the day after final outcome (O+1).

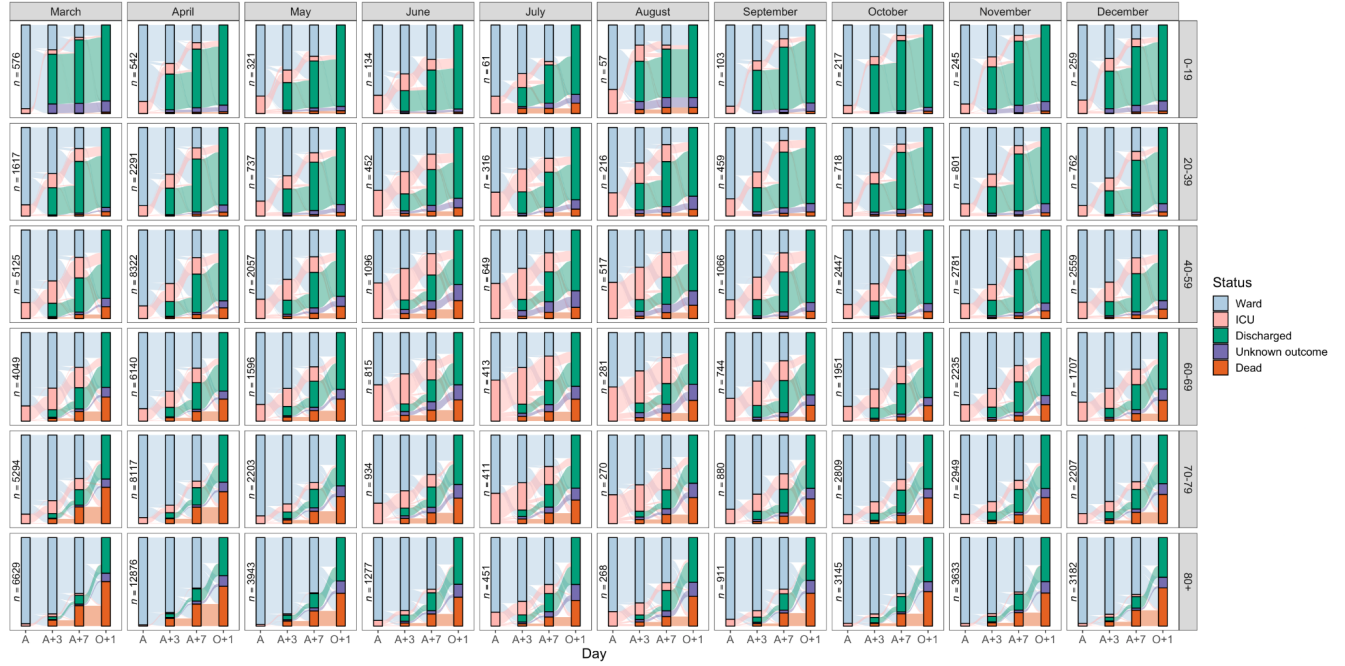

Figure S3: Temporal variation in case fatality rate amongst all patients.

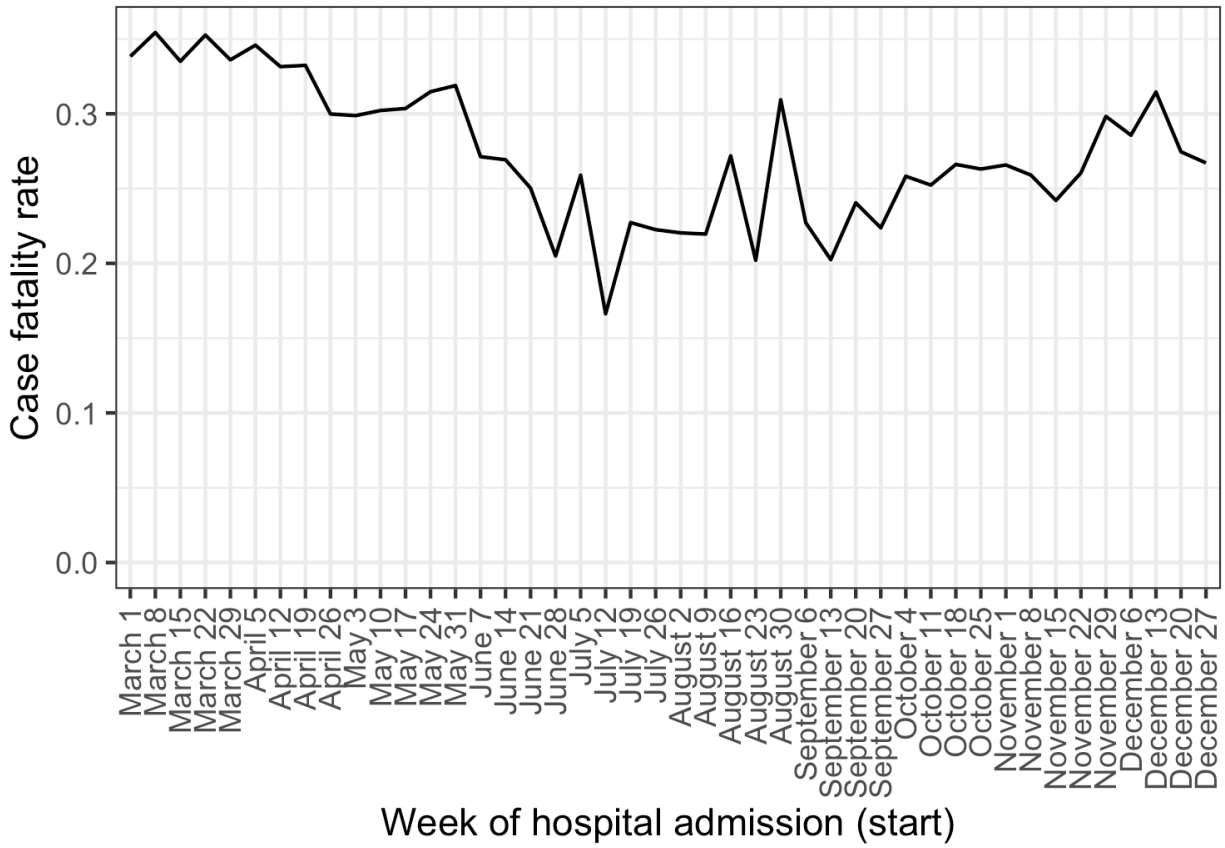

Figure S4: Temporal variation in mean time from COVID-19 admission to outcome (death or discharge) amongst all patients.

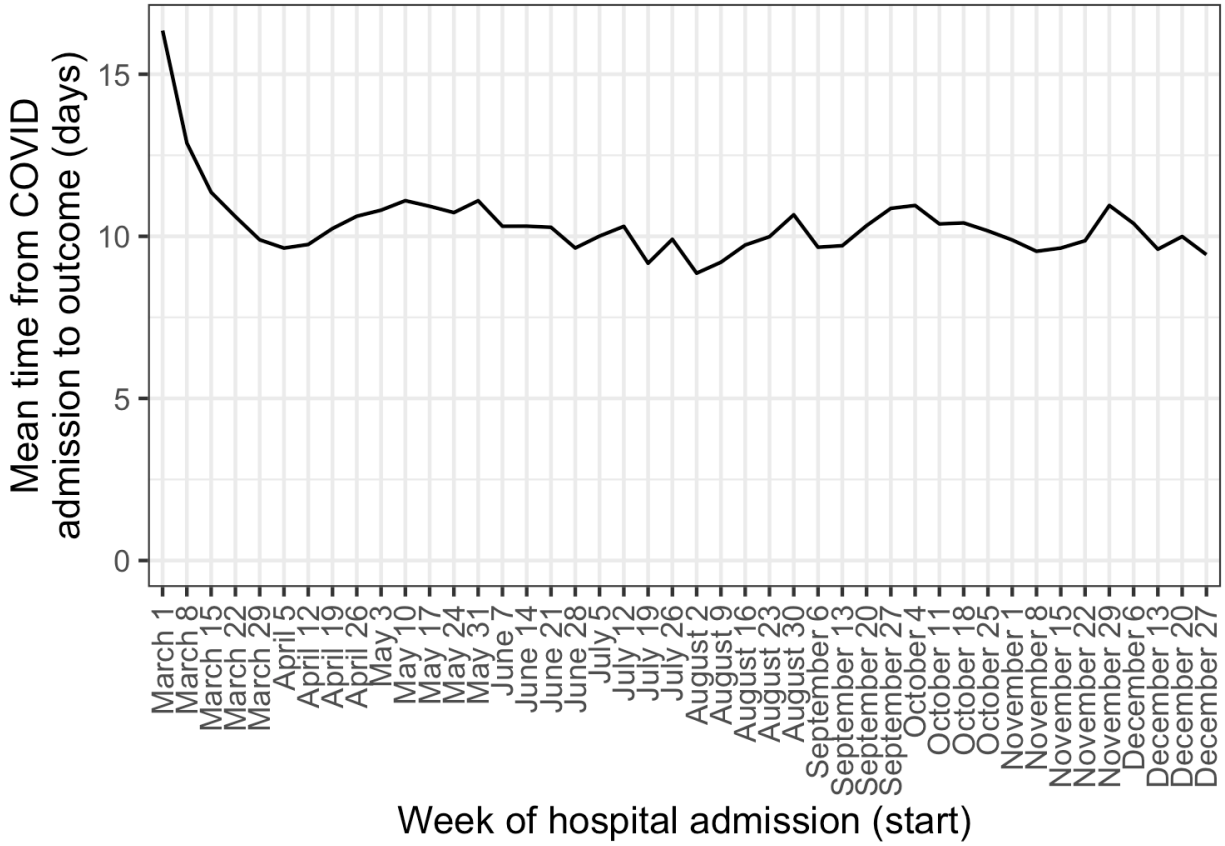

Figure S5: Temporal trends in case fatality rate, faceted by ICU/HDU admission and further separated by age group

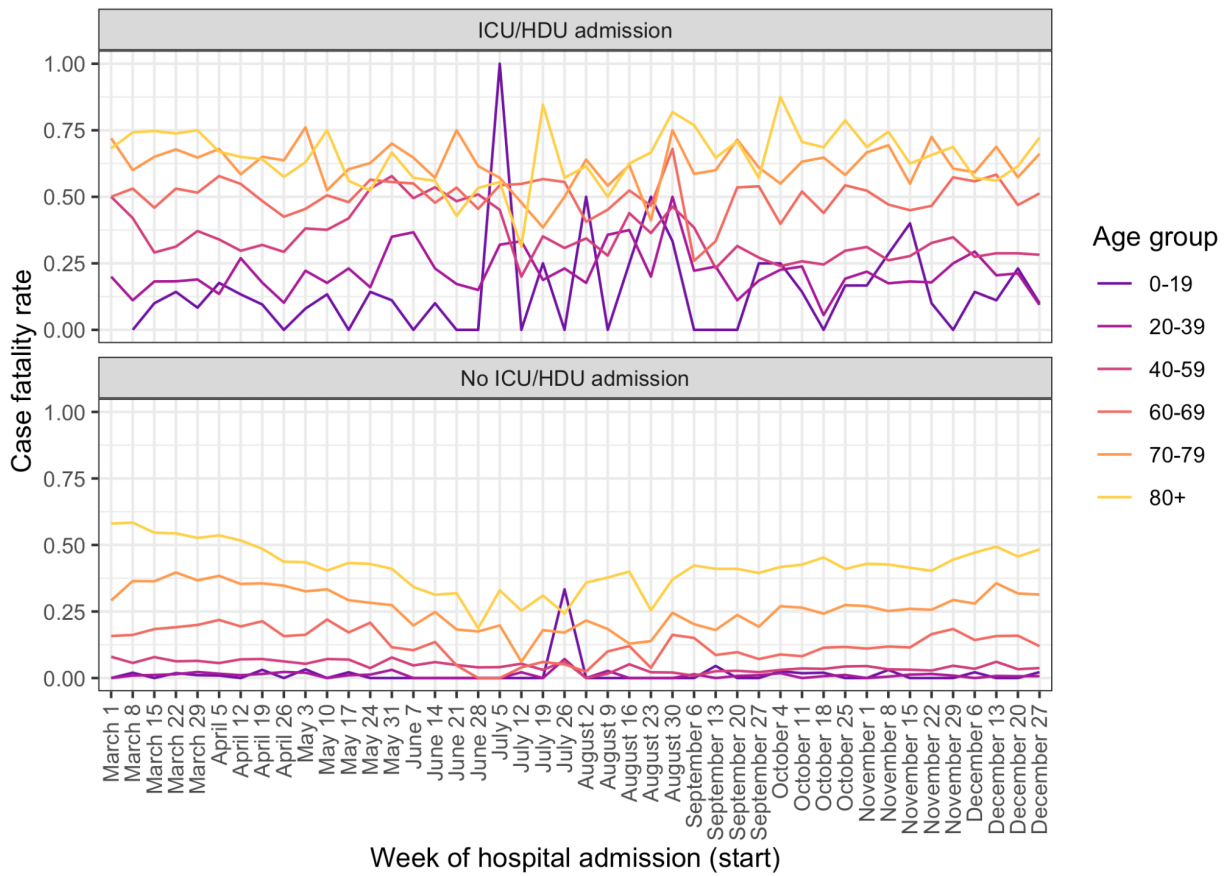

Figure S6: Temporal trends in mean time from COVID-19 admission to outcome, faceted by ICU admission and outcome and further separated by age group.

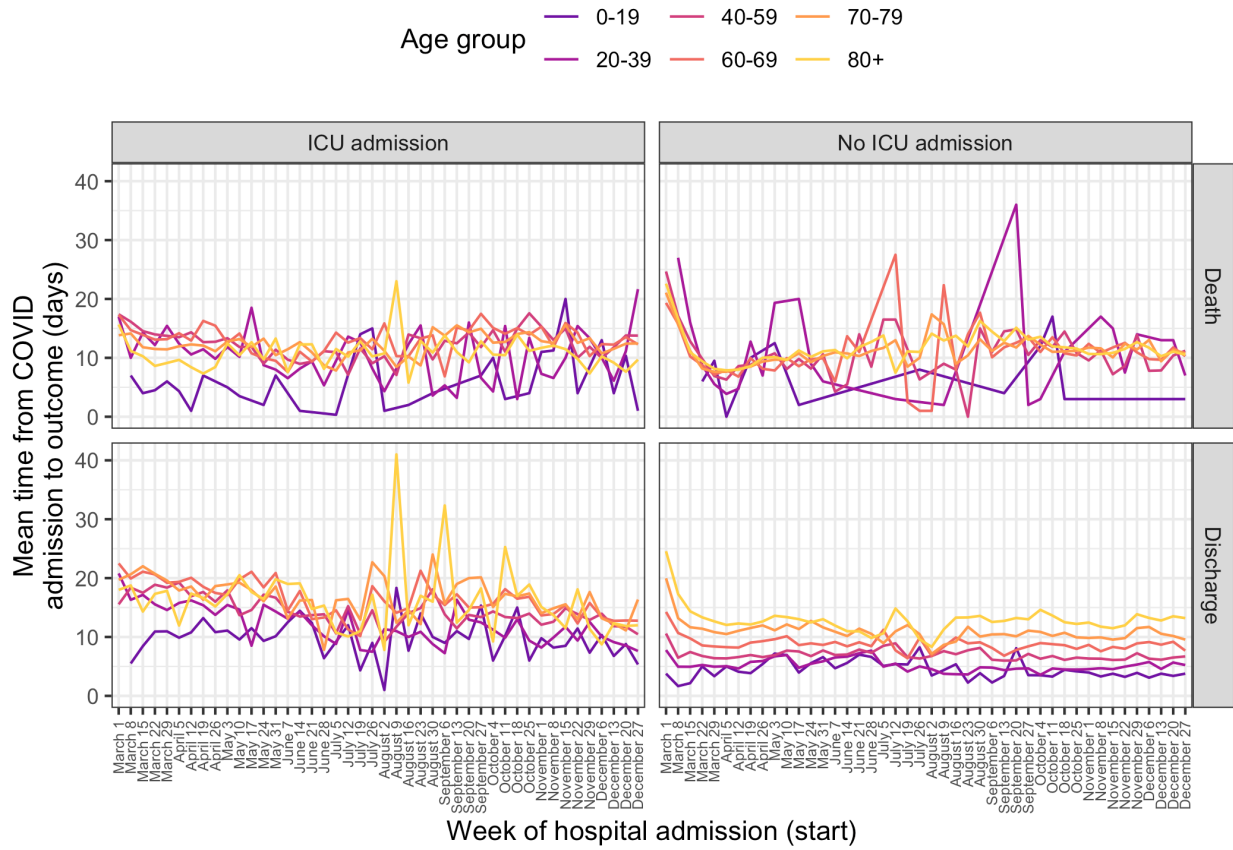

Table S1: Extended table of patient characteristics, by month of COVID-19 admission and overall. Raw numbers are given with percentages in brackets.

Table S2: Summary of the components of the inpatient journey and their variation over the course of 2020. All time periods are in days. Patients are categorised by month of symptom onset for onset to admission, and by month of COVID admission in all other cases. Patients with COVID admission in 2021, who are included in the analysis of time from onset to admission if their onset date was in 2020, are not listed here as they are excluded from any analysis where the outcome variable is not time from onset to admission. “Outcome” is either death or discharge, and the “admission to outcome” column gives the total length of hospital stay. For all durations, the top 2.5% of values are excluded as potentially misentered.

Month	Onset to hospital admission		Proportion entering ICU	COVID-19 admission to ICU		COVID-19 admission to death		COVID-19 admission to discharge		COVID-19 admission to outcome	
	Mean	SD		Mean	SD	Mean	SD	Mean	SD	Mean	SD
March	6.82	5.15	0.262	1.79	2.35	10.6	8.41	10.9	9.71	10.8	9.29

Table S4: Results of a linear regression analysis identifying variables associated with time from symptom onset to hospital admission. The dependent variable was log-transformed after the addition of 1 day to prevent log-transforming zero values. Coefficients have been transformed to reflect the percentage increase or decrease in the number of days to admission, compared to the reference category for categorical variables, or per one point increase for discrete or continuous variables. Countries with less than 200 patients in the dataset have been grouped by region.
