1 **Abstract**

2  
3 Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is the causative agent of the  
4 catastrophic coronavirus disease 2019 (COVID-19) global pandemic. This study aimed to  
5 provide epidemiologic and clinical characteristics of patients with confirmed COVID-19 in  
6 Saudi Arabia and to determine whether characteristic profiles differ between patients who are  
7 symptomatic vs. asymptomatic for the disease. The first 492 consecutive patients diagnosed with  
8 SARS-CoV-2 infection at King Faisal Specialist Hospital and Research Centre in Saudi Arabia  
9 between March and September 2020 were included in this study. An electronic case report form  
10 developed using REDCap was used to collect data for each patient, including demographic  
11 characteristics, virus exposure (travel history, and human and animal contact), vaccination  
12 history, comorbidities, signs and symptoms, laboratory and radiographic reports, cardiac workup,  
13 medications, treatment regimens, and patient outcome. This patient cohort was 54% male, with  
14 20.4% aged more than 60 years, 19.9% aged 31 to 40 years, and 17% aged 41 to 50 years. Most  
15 patients (79.2%) were symptomatic. Variables that significantly differed between symptomatic  
16 and asymptomatic patients were age, blood oxygen saturation percentage, hemoglobin level,  
17 lymphocyte count, neutrophil to lymphocyte (N/L) ratio, alanine aminotransferase (ALT) level,  
18 and aspartate aminotransferase (AST) level. Asymptomatic patients were mostly younger, with  
19 lower body mass index and ALT and AST levels but higher lymphocyte counts, N/L ratio, and  
20 CD4, CD8, natural killer cell, IgG, and IgM levels. The median incubation period reported for  
21 this cohort was 16 day, with upper and lower 95% quartiles of 27 and 10 days, respectively.  
22 Factors associated with increased risk of mortality were age (older than 42 years) and  
23 comorbidities, including specifically diabetes mellitus and hypertension. Patients who were not  
24 given an antiviral regimen were associated with better prognosis than patients who received an  
25 antiviral regimen (HR, 0.07; 95% CI, 0.011-0.25). Similar to countries worldwide, Saudi Arabia  
26 has explored treatment options to save the lives of patients during the COVID-19 pandemic. Our  
27 analyses will inform clinicians as well as policy makers to adopt the best strategies for SARS-  
28 CoV-2 infection management and treatment options.

29  
30 **1. INTRODUCTION**

31 Soon after the novel corona virus, severe acute respiratory syndrome coronavirus 2 (SARS-CoV-  
32 2), emerged in Wuhan, China, in December 2019, its transmission from human to human  
33 established a foothold worldwide [1, 2]. In Saudi Arabia, the first case of a SARS-CoV-2–  
34 infected person was reported on March 2, 2020, a Saudi national who had returned to the country  
35 from Iran [3]. As of July 11, 2021, there have been over 500,000 confirmed cases, 481,241  
36 recovered cases, and 7963 deaths in Saudi Arabia [4]. The number of confirmed positive cases  
37 had been escalating until now, July 2021, despite the country’s strict control measures.

38  
39 Viral epidemiology and clinical manifestation play critical roles in the battle against SARS-CoV-  
40 2. Several studies have reported that patients infected with SARS-CoV-2 have primarily mild  
41 symptoms and good prognosis. Overall, a small fraction of infected patients have been reported  
42 to show severe pneumonia, pulmonary complications, acute respiratory distress syndrome, or  
43 multiple organ failure or to have died [2]. As of July 11, 2021, worldwide statistics showed a  
44 total of 185 million cases and 4 million deaths [5].

45  
46 When the world was struck by this pandemic, hospitals leaders around the globe were  
47 unprepared for the scope of the infection. Indeed, there is still much to learn to manage the

48 consequences of infections by this continually evolving virus. A lack of effective antiviral  
49 medication led to numerous clinical trials of different regimens using available and repurposed  
50 drugs to reach the best management of the disease caused by the virus, coronavirus 2019  
51 (COVID-19). At King Faisal Specialist Hospital and Research Centre (KFSHRC), different  
52 treatment options following international and local guidelines and recommendations were  
53 offered to patients, including azithromycin, hydroxychloroquine (HCQ), azithromycin plus  
54 HCQ, interferon, lopinavir/ritonavir, lopinavir/ritonavir plus ribavirin, and azithromycin plus  
55 HCQ plus lopinavir/ritonavir [6-11].

56  
57 The present study aimed to identify the epidemiologic characteristics, clinical features,  
58 laboratory test results, treatment regimens, and clinical outcomes for patients admitted to  
59 KFSHRC, a tertiary and referral hospital in Saudi Arabia, between March and September 2020,  
60 and to determine whether patient profiles differed significantly between patients who were  
61 symptomatic and those who were asymptomatic.

62

## 63 **2. MATERIALS AND METHODS**

### 64 **2.1 Ethical Considerations**

65 This study was conducted according to the World Medical Association Declaration of Helsinki  
66 and conforms to the ethics recommendations of the Committee on Publication Ethics and the  
67 International Committee of Medical Journal Editors. The study protocol was approved by the  
68 Research Advisory Council (Ethics Committee) at KFSHRC (RAC #220 1047), which also  
69 waived the requirement for obtaining informed patient consent because the risk to individuals  
70 whose data were included in the study was minimal and the study used exclusively retrospective  
71 deidentified administrative records.

72

### 73 **2.2 Data Collection**

74 Data regarding patients with confirmed COVID-19 (positive SARS-CoV-2 polymerase chain  
75 reaction results) were obtained from KFSHRC electronic medical records from March to  
76 September 2020. Data collectors were trained to ensure the completeness and accuracy of the  
77 data collected. An electronic case report form was developed using REDCap (a secure and  
78 flexible web-based clinical research data capture platform) that had over 500 data items for each  
79 patient, including demographic characteristics, potential virus exposure (travel history and  
80 human and animal contact), vaccination history, comorbidities, signs and symptoms, laboratory  
81 and radiologic reports, cardiac workup, medication, treatment regimen, and patient outcome. An  
82 unambiguous identification code was used that enabled identification of all data reported for  
83 each patient. The risk to study participants was limited to the potential loss of confidentiality.  
84 Appropriate measures were taken to prevent loss of participant confidentiality, including storage  
85 of electronic case report forms in a secure manner and presentation of data without identification  
86 of individual patients.

87

### 88 **2.3 Data and Statistical Analyses**

89 All collected data were stored and analyzed using SAS, version 9.4, software and GraphPad,  
90 version 9.0 (Prisma). Inferential and descriptive statistics were conducted to assess the  
91 epidemiologic and clinical manifestations of SARS-CoV-2 infections in Saudi Arabia. We  
92 performed *t* tests and Mann-Whitney tests to assess continuous variables, and  $\chi^2$  tests to assess

93 categorical variables. Univariate and multivariate analyses were performed using Cox  
94 proportional hazards regression models to identify factors associated with death from COVID-  
95 19. The hazard ratio (HR) along with the 95% confidence interval (CI) are reported. All reported  
96 *P*-values were two-tailed and were considered to be statistically significant at <0.05. Logistic  
97 regression models were used to assess the prediction value of immunological parameters.  
98

99 For estimating the time-varying reproduction number, we used the EpiEstim package, version  
100 2.2.1, with R software, version 3.3 [12]. The model estimated the time-varying reproduction  
101 number from the daily number of cases of COVID-19 reported at KFSHRC and an uncertain  
102 generation time with a mean of 4.6 days and a standard deviation (SD) of 2.9 days based on other  
103 studies [13]. We used a gamma distribution prior for the reproduction number with a mean of 2.6  
104 and SD of 2.0 based on early estimates for the basic reproduction number ( $R_0$ ) from the initial  
105 stages [14].  
106

### 107 **3. RESULTS**

#### 108 **3.1 Summary of Demographic Characteristics and Clinical Data**

109 Data from 492 patients were collected from the portal from March 10 to September 11, 2020.  
110 Table 1 provides a summary of patient demographic and clinical characteristics for the cohort.  
111 Of 492 patients, 54.0% were male. Most patients (20.4%) were older than 60 years, followed by  
112 ages ranging from 31 to 40 years (20.0%) and from 41 to 50 years (17.9%). The highest  
113 proportion of patients in this cohort received at KFSHRC were from Saudi Arabia (77.8%),  
114 followed by the Philippines (29.4%), and India (22.4%). Of those from Saudi Arabia, the  
115 majority were from Riyadh (79%), followed by Jeddah (15.1%). The clinical data indicated that  
116 the majority of patients symptomatic for COVID-19 presented with a temperature lower than 38  
117 °C (54.8%) and without a dry cough (51.6%). Only 21.2% reported myalgia fatigue, and 23.6%  
118 had chest radiographs with indications of concern. Intensive care unit (ICU) admission was  
119 received by 21.8% of the cohort, and 12.1% received mechanical ventilation. We found that  
120 42.0% of patients presented with comorbidities, including 20.6% with diabetes and 24.4% with  
121 hypertension. For patient outcomes on day 14 of hospitalization, 33.2% showed persistent  
122 disease, 16.1% recovered, 8.4% were discharged from the hospital, and 1.5% died.  
123

#### 124 **3.2 Demographic and Clinical Characteristics of Symptomatic vs. Asymptomatic Patients**

125 The second aim of our study was to determine the demographic and clinical characteristics of  
126 symptomatic vs. asymptomatic persons. Of 429 individuals in the cohort, 79.2% reported being  
127 symptomatic and 20.7% being asymptomatic. A summary of the analysis assessing continuous  
128 variables by symptomatic status is given in Table 2. Characteristics that were significantly  
129 different between symptomatic and asymptomatic patients were age, blood oxygen saturation  
130 percentage, hemoglobin level, lymphocyte level, the neutrophil to lymphocyte (N/L) ratio,  
131 alanine aminotransferase (ALT) level, and aspartate aminotransferase (AST) level.  
132 Asymptomatic patients were primarily younger, with lower body mass index and ALT and AST  
133 levels, but higher N/L ratios and higher lymphocyte, CD4, CD8, natural killer cell, IgG, and  
134 IgM levels.  
135

136 Table 3 provides a summary of categorical data by symptom status. Many demographic and  
137 clinical characteristics were significantly different between the two groups, including, age, sex,  
138 smoking status, influenza vaccine receipt, comorbidities, diabetes, hypertension, chest

139 radiographic findings, pneumonia treatment, and outcome on days 7 and 14. The highest  
140 proportion of asymptomatic patients were from age group 31–40 years and were men. Most  
141 asymptomatic patients were nonsmokers, had received an influenza vaccine, and had no history  
142 of comorbidities, including diabetes or hypertension.

143  
144

### **3.3 Variation in Disease Incubation Times**

145 The median incubation period reported in our population was 16 days (SD, 17 days), the upper  
146 and lower 95% quartiles were 27 and 10 days, respectively. The incubation period differed  
147 significantly only with age: patients 42 years or younger reported lower incubation times than  
148 those older than 42 years. The incubation period did not differ significantly between any other  
149 examined demographic or clinical variable, including the number of treatment regimens (Table  
150 4).

151  
152

### **3.4 Demographical and Clinical Characteristics Associated with Death Due to COVID-19**

153 The epidemiologic and clinical factors associated with death among patients with COVID-19 are  
154 summarized in Table 5. The only demographic characteristic that was statistically significantly  
155 associated with death for patients with COVID-19 was being older than 42 years (HR, 10.32;  
156 95% CI, 2.4-44.3) although the risk of death appeared higher for men than women, Saudi  
157 nationals vs. non-Saudi persons, and individuals with vs. without obesity. Assessment of clinical  
158 data indicated that being symptomatic or asymptomatic was not significantly associated with  
159 higher risk of death, whereas having comorbidities in general was significantly associated with  
160 higher risk of death (HR, 3.42; 95% CI, 1.24-12.1) as was specifically having diabetes mellitus  
161 (HR, 3.9; 95% CI, 1.68-9.4) or hypertension (HR, 5.135; 95% CI, 2.2-12.5). None of the  
162 common complications of COVID-19 (e.g., fever, myalgia fatigue, sore throat, and vomiting)  
163 were significantly associated with death, although among these complications, higher risk of  
164 poor prognosis was observed for patients with chest radiograph results indicating abnormalities,  
165 followed by patients with dry cough and nausea. Regarding treatment options, patients who were  
166 not given an antiviral regimen had better prognoses (HR, 0.07; 95% CI, 0.011-0.25) than patients  
167 who received an antiviral regimen, followed by patients receiving interferon regimens.  
168 Significant and high risk of death was associated with receipt of a combination therapy of  
169 azithromycin, hydroxychloroquine, and lopinavir/ritonavir (HR, 149.6; 95% CI, 5.8-3808.4),  
170 whereas lower risk of death was associated with receipt of a combination of two or more  
171 therapies (HR, 2.7; 95% CI, 1.1-6.6). For receipt of a single treatment, among those examined,  
172 lopinavir/ritonavir (HR, 19.28; 95% CI, 0.98-130.4) and azithromycin (HR, 3.5; 95% CI, 0.819-  
173 10.4) were associated with the worst prognosis. Patients receiving pneumonia treatment were  
174 associated with poor prognosis (HR, 9.1; 95% CI, 3.28-32.3), and patients receiving mechanical  
175 ventilation had the second highest HR (HR, 90; 95% CI, 18.4-1624.2).

176  
177  
178

### **3.5 Association of Immunological Factors with Patient Outcomes, Symptoms, and Treatment Regimen**

179 Using multivariate Cox regression, we evaluated white blood cell (WBC), absolute lymphocyte,  
180 and neutrophil counts and the NTL ratio as factors potentially associated with patient outcomes  
181 and with type of treatment regimen. The values of these factors were obtained from patients after  
182 they received a diagnosis of COVID-19. If a univariate model indicated that a factor was  
183 significantly associated with patient outcome, we pursued additional testing for treatment type.

184

185 The results of a univariate Cox regression assessing WBC count indicated a significant  
186 association with patient outcome ( $\chi^2=11.9$ ,  $P=0.0005$ ). The multivariate model testing treatment  
187 types showed significance for all treatment types ( $P<0.05$ ). For patients receiving  
188 lopinavir/ritonavir treatment alone, the HR was significant (HR=35.3; 95% CI, 1.7-312.4),  
189 whereas the HR for WBC count was 1.2 (95% CI, 1.1-1.3). The other significant HR was for  
190 receipt of combination therapy with lopinavir/ritonavir, HCQ, and azithromycin (HR=154.5;  
191 95% CI, 5.9-4013). For Patients receiving treatment with HCQ or azithromycin alone or with the  
192 combination of HCQ and azithromycin or with interferon or for pneumonia, HRs were not  
193 statistically significant ( $P>0.05$ ).

194  
195 A univariate cox regression model assessing the association of lymphocyte count with patient  
196 outcome showed no significance ( $\chi^2=0.39$ ,  $P=0.53$ ). In addition, none of the multivariate models  
197 were significant ( $P>0.05$ ). Similarly, none of the models indicated an association with the NTL  
198 ratio.

199  
200 By contrast, for the neutrophil count, a univariate cox regression model assessing the association  
201 with patient outcome was statistically significant ( $\chi^2=6.7$ ,  $P=0.0092$ ). The multivariate models  
202 assessing an association with treatment types were significant for all treatment types ( $P<0.05$ ).  
203 However, the only significant treatment factors were lopinavir/ritonavir and the combination of  
204 HCQ, azithromycin, and lopinavir/ritonavir. For patients receiving lopinavir/ritonavir treatment  
205 alone, the HR was significant (HR=23.5; 95% CI, 1.1-196), whereas the neutrophil HR was 1.3  
206 (95% CI, 1.1-1.5). For patients receiving the combination therapy, the HR was significant (HR,  
207 92.8; 95% CI, 3.6-2348), whereas the neutrophil HR was 1.3 (95% CI, 1.1-1.5). For patients  
208 receiving HCQ treatment, interferon treatment, any two-drug combination therapy, or pneumonia  
209 treatment, the HRs were not significant ( $P>0.05$ ).

210  
211 We also evaluated models assessing associations of levels of immunological factors with patient  
212 symptom status. Neither the WBC levels nor the neutrophil count were associated with patient  
213 symptoms status. An immunological parameter that was significantly associated with patient  
214 symptom status was the NTL ratio ( $\chi^2=17.3$ ,  $P<0.0001$ ); higher NTL ratios were correlated with  
215 symptomatic disease (OR=0.6, 95% CI: 0.4-0.8). There was also a significant association  
216 between patient symptom status and lymphocyte levels alone ( $F=17.9$ ,  $P<0.0001$ ;  $R^2=0.058$ );  
217 higher WBC count was correlated with asymptomatic disease.

218  
219 We evaluated the use of a mechanical ventilator as a proxy for the severity of disease and found  
220 that it was significantly associated with the NTL ratio ( $\chi^2=14.9$ ,  $P<0.0001$ , OR=1.2, 95% CI:1.1-  
221 1.3), with higher NTL ratios correlating with severe disease. Similarly, higher WBC counts  
222 ( $\chi^2=42.9$ ,  $P<0.0001$ , OR=1.4, 95% CI:1.2-1.6) and higher neutrophil counts ( $\chi^2=28.5$ ,  $P<0.0001$ ,  
223 OR=1.5, 95% CI:1.3-1.8). were correlated with greater disease severity. Although higher  
224 lymphocyte levels appeared to be associated with less severe disease, the association was not  
225 significant ( $\chi^2=2.3$ ,  $P=0.09$ ).

226  
227 For patient outcomes, the model assessing the association of the WBC count ( $\chi^2=13.3$ ,  $P=0.003$ ,  
228 OR=1.2, 95% CI:1.2-1.4) and that assessing the level of neutrophils ( $\chi^2=11.0$ ,  $P=0.0009$ ,  
229 OR=1.4, 95% CI=1.4-1.7). were significant, with higher levels correlated with patient death.  
230 However, neither the NTL ratio nor lymphocyte level was associated with patient death. Figure 2  
231 shows the distribution of the immunological factors by disease severity and tested by the Mann-  
232 Whitney test. Three multilevel logistic models were assessed with all immunological parameters,

233 and they were all significant predictor for patient's outcome, or severity or symptoms together  
234 ( $P<0.005$ ).

235  
236 A multivariate model using multilevel regression was used to assess the association of  
237 immunological factors with the incubation period. The lymphocyte count with age was the only  
238 factor significantly associated with the incubation period ( $F=4.8$ ,  $P=0.009$ ). Neutrophil and WBC  
239 counts and the NTL ratio were not associated.

### 240 241 **3.6 Reproduction Number Estimations and Predicting COVID-19 in Riyadh**

242 We estimated the instantaneous temporal effective reproduction number ( $R_t$ ) using the EpiEstim  
243 package and modeled it using a gamma distribution. For 155 days, confirmed COVID-19 cases  
244 were detected at KFSHRC. Figure 3 shows the summary of the incidence and R values over  
245 time. The average value for R from March 11 to August 10, 2020, was 1.21. In March, R  
246 averaged 1.94, decreasing in April to 0.81, but increasing in May to 2.24, before decreasing in  
247 June to 1.07 and in July to 0.92. The highest value of R was found in May, which is when the  
248 government implemented strict lockdown protocols to substantially decrease the number of  
249 confirmed COVID-19 cases in June and July, accompanied by a significant decrease in the value  
250 of R. In August, a significant decrease in cases was observed followed by an increased risk of R  
251 followed its mean values reported. We also estimated the effective reproduction number over  
252 time in Saudi Arabia overall. The pattern across the entire country was similar to that estimated  
253 for KFSHRC (Figure 4). However, R peaked at a national level in March then decreased in May  
254 after the lockdown and kept decreasing in June and July. The average value of R in Saudi Arabia  
255 between March and July was 1.23.

## 256 257 **4. DISCUSSION**

258  
259 KFSHRC is a tertiary care hospital in Riyadh, Saudi Arabia, that typically provides specialized  
260 care for cancer, organ transplantation, and patients who are immunocompromised in addition to  
261 offering other medical specialties. However, to increase treatment capacity for Saudi Arabia  
262 during the pandemic, KFSHRC allowed access to COVID-19 patients when it is needed. The  
263 first case was admitted in March 2020. By investigating the demographic and clinical  
264 characteristics of the first 492 patients with confirmed COVID-19, our study found that the  
265 number of male patients was higher (54%) than female patients (46%), consistent with several  
266 studies reporting from various parts of the world and indicating that men have higher morbidity  
267 and mortality associated with COVID-19 than women [15-17]. The male vs. female differences  
268 may be attributable to biological differences, including of the immune system, which impacts the  
269 body's ability to fight an infection, including SARS-2-CoV-2. It has been reported that women  
270 are more resistant to infections than men, and this is potentially mediated by several factors,  
271 including different sex hormone levels and higher expression of coronavirus receptors  
272 (angiotensin-converting enzyme, ACE receptors) in men but also lifestyle aspects, such as higher  
273 levels of smoking and drinking among men compared with women [17]. Another vulnerability  
274 factor observed in our study was age, with the highest percentage of patients with confirmed  
275 COVID-19 being older than 60 years (20.4%), followed by patients aged 31 to 40 years (19.9%)  
276 and those aged 41 to 50 years (17%), a finding consistent with several other studies. There is  
277 evidence that the susceptibility to COVID-19 and the increased mortality risk in older people is  
278 linked to frailty [18]. Regarding clinical characteristics, we found that most symptomatic patients  
279 did not present with fever higher than 38 °C (54.8%) or dry cough (51.6%), and only 21%  
280 reported myalgia fatigue and 23.6% had abnormal findings on chest radiography. The latter

281 finding was expected because COVID-19 may cause pneumonia that manifests clinically even in  
282 asymptomatic patients [19].

283 Among 492 patients, 21% were admitted in ICU attention, and 12% received mechanical  
284 ventilation. Approximately 42% of patients had comorbidities, including 20% with diabetes and  
285 24% with hypertension. These results agree with a recent study from Spain in which they  
286 retrospectively described 49 consecutive patients admitted to the internal medicine hospital ward  
287 for COVID-19 infection and found a significant association between diabetes and the need for  
288 admission to the ICU [20]. One of the largest studies of this type, conducted in 138 hospitals in  
289 France, Belgium, and Switzerland and including over 4000 patients critically ill with COVID-19  
290 admitted to an ICU, reported that patients who were older or had diabetes or obesity were at the  
291 highest risk of mortality [21]. In addition, our data showed patient outcomes at day 14 included  
292 persistent disease (33%), recovered (16%), discharged (8.4%) or death (1.5%). Our work also  
293 investigated variations in incubation time and its association with different variables. We found  
294 that the median incubation period reported in our population was 16 days (SD, 17 days), the  
295 upper 95% quartile was 27 days, and the lower quartile was 10 days. The incubation period was  
296 significantly associated only with age, with younger patients reporting a lower incubation period.  
297 Other investigated variables were not significantly associated with the incubation period. A  
298 systematic review and meta-analysis was recently published evaluating epidemiologic  
299 parameters to determine transmission and incubation dynamics [22]. For more than 23 studies  
300 combined, the mean incubation period of COVID-19 ranged from 4.8 to 9 days.

301  
302 The present study determined whether patient profiles differed significantly for those who were  
303 symptomatic vs. asymptomatic. In a total of 429 patients, 79.2% reported having symptoms, and  
304 20.7% reported being asymptomatic. Not every asymptomatic patient went to the hospital to be  
305 checked for the presence of SARS-CoV-2, which may explain the discrepancy between mild vs.  
306 severe patient outcomes. According to the WHO, most people infected with the SARS-CoV-2  
307 virus will experience mild to moderate respiratory illness and recover without requiring special  
308 treatment; older people, and those with underlying medical problems, such as diabetes, chronic  
309 respiratory disease, cardiovascular disease, and cancer, are more likely to develop serious illness  
310 [23]. The age group and sex having the highest proportions of asymptomatic patients were 31-to-  
311 40-year-olds and males. Compared with symptomatic patients, asymptomatic patients were  
312 younger, nonsmokers, received an influenza vaccine, had no history of comorbidities, including  
313 diabetes or hypertension, and had lower BMI, ALT, and AST levels. Asymptomatic patients also  
314 had a higher NTL ratio and higher lymphocyte, CD4, CD8, natural killer cell, IgG, and IgM  
315 levels.

316  
317 This study reported the most important epidemiologic and clinical factors associated with  
318 mortality in a cohort of patients with COVID-19. Our data showed that age and comorbidities  
319 were significantly associated with higher risk of death in this cohort, with both diabetes mellitus  
320 and hypertension associated with higher risk of death. Previous studies have shown that  
321 populations over 65 years old with comorbidities such as diabetes or hypertension have higher  
322 mortality rates in COVID-19 cases. The largest study of COVID-19 cases from China (72,314  
323 cases) showed increased incidence of mortality among patients with diabetes and COVID-19  
324 (2.3% without diabetes vs. 7.3% with the disease) [24]. Other studies from the United States,  
325 Italy, and China have reported that the diabetic population is at greater risk not only for disease  
326 complications but also for infection susceptibility [25].

327

328 Although an effective antiviral treatment for COVID-19 is not currently available, some  
329 repurposed medications have been proposed for use at KFSHRC. We observed different patient  
330 outcomes associated with each treatment regimen. Patients who did not receive an antiviral  
331 regimen had better prognoses, followed by patients receiving an interferon regimen. A  
332 significant and high HR was observed for patients receiving a combination therapy of  
333 azithromycin, hydroxychloroquine, and lopinavir/ritonavir, and a lower HR was observed for  
334 patients receiving a combination therapy of two or more drugs. Among patients who received  
335 only a single drug regimen, those receiving lopinavir/ritonavir or azithromycin had the worst  
336 prognosis. Our findings are consistent with the reported international data and clinical trials [26-  
337 29]. Patients receiving pneumonia treatment had poor prognosis overall, and patients receiving  
338 mechanical ventilation had also the second-highest rate. We concluded from our data on the  
339 treatment regimens that azithromycin, hydroxychloroquine, and lopinavir/ritonavir were not  
340 effective treatment for COVID 19, and this is consistent with previous studies and the solidarity  
341 trial [30, 31]

342  
343 There are limitations in the current database and the main limitation is that this retrospective  
344 study was conducted during the early COVID-19 pandemic where various effective interventions  
345 were not assessed such as dexamethasone, IL6 inhibitors, Jak inhibitors and Remdesvir.

#### 346 347 **Conclusion**

348 This study reports significant differences between patients symptomatic and asymptomatic for  
349 COVID-19 in a cohort with a relatively large number at a Saudi tertiary care hospital, improving  
350 the understanding of the epidemiologic and clinical features associated with SARS-CoV-2  
351 infection. This study also assesses treatment regimens used early in the COVID-19 pandemic to  
352 inform scientific and medical databases and future clinical use and research.

#### 353 354 **Contribution to the Field**

355 This work provides epidemiologic and clinical characteristics data from patients in Saudi Arabia  
356 with confirmed SARS-COV-2 infection to inform treatment regimens and case management.  
357 Scarce studies from Saudi Arabia have highlighted case management and treatment regimens,  
358 especially for symptomatic vs. asymptomatic patients. The data provided here were obtained  
359 from a comprehensive database developed in-house for King Faisal Specialist Hospital and  
360 Research Centre, a single-center, tertiary and referral care hospital. We created the electronic  
361 medical records database to collect from each patient their demographic characteristics, virus  
362 exposure (travel history, and human and animal contact), vaccination history, comorbidities,  
363 signs and symptoms, laboratory and radiographic reports, cardiac workup, medications,  
364 treatment regimens, and outcome. The database continues to be used for all patients with  
365 confirmed SARS-COV-2 infection. Here, we describe our analyses of the demographic and  
366 clinical characteristic data obtained from the first 492 consecutive patients at the hospital  
367 diagnosed with SARS-CoV-2 infection. These findings provide insights on the epidemiologic  
368 and clinical characteristics and case management of patients in Saudi Arabia with confirmed  
369 SARS-COV-2 infection to inform future treatment regimens worldwide.

#### 370 371 372 373 **Conflict of Interests**

374 The authors declare that the research was conducted in the absence of any commercial or  
375 financial relationships that could be construed as a potential conflict of interest.

376

### 377 **Author Contributions**

378 FA is the principal investigator of this study. RA and ED are co-principle investigators who  
379 helped in the study design and validation. BA, SA, MM, and AA are physicians and clinical  
380 scientists who reviewed medical charts and helped in clinical data interpretation. DO performed  
381 the statistical analysis. AA and SA built the database, trained the data collectors, and oversaw  
382 data collection and data quality. All authors helped in writing and reviewing the manuscript. In  
383 addition, all authors read and approved the final manuscript.

384

### 385 **Funding**

386 This work was fully funded by a King Faisal Specialist Hospital and Research Centre COVID-19  
387 grant (KFSHRC; RAC #220 1047)

388

### 389 **Acknowledgements**

390 We thank the KFSHRC higher administration for their full support during the pandemic. We also  
391 thank the data collection team who is managing the hospital database [Haya Alajlan, Ruba  
392 Aldossary, Samar Almogbel, Noura Alqahtani, Shatha Alshammari, Rahaf Al-Rashoud, Sanaa  
393 Al-Ali, Hadeel Al-Bedewi, Leen Al-Hogbani, Fai Al-Khathlan, Najla Al-Orayyidh, Noura Al-  
394 Zannan, Raneem Al-Zeer, Shatha Barajaa, and Ishraq Rajeh].

484 **Figure legends**

485 Figure 1. Age group distribution of COVID-19 cases by symptom status (asymptomatic vs.  
 486 symptomatic) shown as percentages. Most patients in this cohort with confirmed COVID-19  
 487 were older than 60 years (19%); 21% of the cohort was asymptomatic, whereas 79% was  
 488 symptomatic. The highest percentage of asymptomatic patients (5%) was observed in the age  
 489 group of 30 to 39 years.

490  
 491 Figure 2. Box plots of patient blood test results after diagnosis by illness severity as assessed by  
 492 the need for mechanical ventilation (MV). A) White blood cell count by illness severity, with  
 493 higher counts observed for more severe illness. B) Neutrophil absolute count by illness severity,  
 494 with higher counts observed for more severe illness. C) Lymphocyte absolute count by illness  
 495 severity, with higher counts observed for milder illness. D) Neutrophil to lymphocyte (NTL)  
 496 ratio by illness severity, with higher ratios observed for more severe illness.

497  
 498 Figure 3. Instantons reproduction number ( $R_t$ ) estimated using the EpiEstim package and  
 499 modeled using a gamma distribution. Cases were detected for 155 days at KFSHRC. The average  
 500 R value from March 10 to August 11, 2020, was 1.21. The red line shows the average median of  
 501 R; dashed red line, confidence intervals; green line, incidence of cases reported; gray area, the  
 502 lockdown period; and blue line,  $R=1$ .

503  
 504 Figure 4. The estimated instantons reproduction number ( $R_t$ ), using EpiEstim package and model  
 505 using gamma distribution. Cases were detected for 155 days in Saudi Arabia. The average R-  
 506 value from March 10 to August 11, 2020, was 1.23. The red line shows the average median of R,  
 507 the dashed red line shows the confidence intervals, while the green line shows the incidence of  
 508 cases reported, the grey area represents the time of lockdown, while the blue line represents the  
 509  $R=1$ .
