ClinicalTrials.gov Protocol Registration and Results System

ClinicalTrials.gov ID: NCT02457832

**Study Identification**

Unique Protocol ID: N0870-W

Brief Title: Motor Training in PD

Official Title: Optimizing Motor Training in Parkinson Disease Through Neural Mechanisms (NEURODEGEN)

**Secondary IDs:**

**Study Status**

Record Verification: June 2021

Overall Status: Active, not recruiting

Study Start: November 3, 2014 [Actual]

Primary Completion: December 31, 2022 [Anticipated]

Study Completion: December 31, 2023 [Anticipated]

**Sponsor/Collaborators**

Sponsor: VA Office of Research and Development

Responsible Party: Sponsor

Collaborators:

**Oversight**

U.S. FDA-regulated Drug: No

U.S. FDA-regulated Device: No

Unapproved/Uncleared Device: No

U.S. FDA IND/IDE: No

Human Subjects Review:

Board Status: Approved

Approval Number: 00060613

Board Name: Emory University Institutional Review Board

Board Affiliation: Emory University

Study Description

Brief Summary: The purpose of this research study is to learn more about brain activity when individuals with and without Parkinson disease (PD) move their lower limbs. The investigators also want to see if and how two different types of partnered dance affect brain activity in individuals with and without PD. Testing will take place at the Atlanta VA Medical Center and at Emory University. The investigators expect to enroll about 140 people for this study over a five-year period.

Detailed Description: Persons with Parkinson’s disease (PD) have impaired mobility, which adversely affects their quality of life. The effectiveness of adapted tango dance, in which participants both lead (internally guide: IG) and follow (externally guide: EG) movement has been shown. To improve outcomes in those with PD, the underlying brain mechanisms for both motor impairments and improvement must be studied. IG and EG movements have distinct brain activity patterns. Individuals with PD have trouble with IG movement but this problem is helped by strategies used while "leading." During "following", participants with PD can use many external cues, which helps movement in PD, because EG tasks bypass the basal ganglia, the part of the brain affected by PD. In older persons with PD, the investigators aim to:

- determine brain activation patterns during IG and EG foot movement.
- look into effects of IG and EG training on brain activation along with mobility improvements.

The investigators will begin with a functional Magnetic Resonance Imaging test in a scanner. The investigators will look at brain area correlates of a clinically-used foot-tapping task, during IG and EG conditions in older persons with and without PD. Then, the investigators will assess the relative effectiveness of IG versus EG training during an adapted tango class, compared to a group that participates in health education, for improved mobility and foot tapping. Participants with PD will be assessed for disease severity. They will receive tests of outcome measures while "OFF" and "ON" PD-specific medications at the following time points:

- 1 week before training
- 1 week after training
- 1 month after training Participants must attend 20 lessons of IG or EG adapted tango in 12 weeks, taught by an experienced instructor. In the functional MRI (fMRI) scanner, the investigators will assess participants for improved foot tapping after training. The investigators will also look at changes in activation in specific brain circuits along with training effects upon mobility.

The long-term goal is to improve motor training as much as possible for persons with PD by understanding foot movement brain circuitry in PD as well as brain changes in circuitry through which training is effective. This work proposes to illumine information about brain function that is very important to continued progress in rehabilitative care of persons with PD.

Conditions

Conditions: Parkinson Disease
Study Design

Study Type: Interventional  
Primary Purpose: Supportive Care  
Study Phase: N/A  
Interventional Study Model: Parallel Assignment  
Number of Arms: 4  
Masking: None (Open Label)  
Allocation: Randomized  
Enrollment: 99 [Anticipated]

Arms and Interventions

<table>
<thead>
<tr>
<th>Arms</th>
<th>Assigned Interventions</th>

</table>
| Experimental: Internal guidance training (IG)  
  Adapted tango dancing is a sophisticated, yet accessible system of tactile communication that conveys motor intentions and goals between a leader and follower. Those in IG training will choose direction, timing and amplitude of each successive step, and will communicate this information to their partner through moving their frame and center of mass. | Behavioral: Adapted Tango Dancing  
Composed of simple steps, tango involves frequent movement initiation and cessation, multi-directional perturbations and varied rhythms. Participants focus on trunk control and stepping strategies, coordination, somatosensory awareness, attention to partner, path of movement, and aesthetics. Sessions will begin with a typical dance class warm-up consisting of breathing, limbering and postural alignment to upbeat music. Novel step elements will be introduced every class period. Those with PD will partner with an individual without PD. After novel step introduction, the instructor will present rhythmic training, which is indispensable to partnered dancing. Participants will learn 'typical' rhythms from tango and Latin dances, based upon the system of quicks (Q) and slows (S), ubiquitously used in ballroom dance training to understand the temporal relationship of movement to music. |
| Experimental: Externally guided training (EG)  
Those in EG will learn to attend to sensory cues for movement direction, timing and amplitude of steps, communicated from their partner to them via the frame and center of mass. The 'follower' will wait to receive the movement cue before moving. | Behavioral: Adapted Tango Dancing  
Composed of simple steps, tango involves frequent movement initiation and cessation, multi-directional perturbations and varied rhythms. Participants focus on trunk control and stepping strategies, coordination, somatosensory awareness, attention to partner, path of movement, and aesthetics. ### Outcome Measures

**Primary Outcome Measure:**

1. **Percent signal change**  
   For the IG and EG tasks for the MRI, the investigators want to determine and distinguish circuits involved in IG and EG foot-tapping networks in participants with and without PD.  
   **[Time Frame: 12 weeks]**

2. **Connectivity strength**  
   Changes in average connectivity strength across striatal-thalamo-cortical (STC) and cerebello-thalamo-cortical (CTC) circuits, as measured by average cross correlation coefficient between the seed regions of the circuits.  
   **[Time Frame: 12 weeks]**

### Eligibility

**Minimum Age:** 40 Years  
**Maximum Age:**  
**Sex:** All  
**Gender Based:** No  
**Accepts Healthy Volunteers:** Yes

**Criteria:**  
- Age 40 - 70 years  
- Willingness to spend 1-h in a scanner  
- Able to walk with or without an assistive device 10 feet  
- Best corrected/aided acuity better than 20/70 in the better eye  
- Absence of dementia or vascular cognitive impairment  
- Absence of primary memory deficits

**Exclusion Criteria:**  
- Deep brain stimulator implants, Metallic implants, fragments, or pacemakers  
- Montreal Cognitive Assessment (MocA) score < 24  
- Pure-tone threshold sensitivity > 40 dB
• Peripheral neuropathy
• Untreated Major Depression
• History of stroke, or traumatic brain injury
