16 Short running title: Suppression of SARS-CoV-2 mutation by vaccination

17 Word count: 977 words.

18

19

20 **Abstract**

21

22 Public distrust has undermined COVID-19 vaccine acceptance and has become a

23 major public health issue in the battle against SARS-CoV-2 transmission globally.

24 Here we present the first evidence that the vaccination coverage rate is inversely

25 correlated to the mutation frequency of the SARS-CoV-2 delta variant in 16

26 countries ( $R^2=0.878$ ), strongly indicating that full vaccination against COVID-19 is

27 critical to suppress emergent mutations. We also present a promising tool to

28 forecast new COVID-19 outbreaks. The Tajima's  $D$  test, an evolutionary algorithm,

29 with a threshold value of -2.50 is shown to be an accurate predictor of new

30 outbreaks. We recommend that universal vaccination, as well as mitigation

31 strategies, and genomic surveillance continue to be employed to prevent further

32 viral transmission.

33

## 34 **Introduction**

35 Legally required vaccination against various infectious diseases is essential to public  
36 health policy in many countries. However, resistance to voluntary COVID-19  
37 vaccination has emerged worldwide, including in the United States. In mid-June  
38 2021, 33% of Americans said they were not willing to be vaccinated [1]. Public  
39 distrust has undermined COVID-19 vaccine acceptance, in association with a belief  
40 that the vaccine is ineffective, dangerous and compromises individual freedom [2].  
41 Therefore, overcoming COVID-19 vaccination resistance has become a major  
42 challenge to prevent global SARS-CoV-2 transmission.

43

44 SARS-CoV-2 is characterized by an average mutation rate of 7.23 mutations per viral  
45 sample [3]. Mutations drive genome variability, generating many different SARS-  
46 CoV-2 variants as the virus evolves to escape vaccine-mediated immunity and  
47 thereby, develop drug or vaccine resistance [4]. The delta (lineage B.1.617.2)  
48 variants were first documented in October 2020 in India and were designated  
49 variants of concern by the World Health Organization due to its increased  
50 transmissibility and virulence [5]. All SARS-CoV-2 mutations result from two major  
51 mechanisms: (1) spontaneous substitution/deletion of nucleotides, and (2) RNA  
52 recombination [3,4,6]. However, it remains unclear exactly how human  
53 interventions (vaccinations, lockdowns, etc.) affect viral mutations.

54

## 55 **Findings**

56 To explore this question, we first analyzed the correlation between the rates of full  
57 vaccination and the point mutation frequency ( $Mf$ ) of COVID-19 delta variants'  
58 genome in 20 countries. Complete SARS-CoV-2 genome sequences with high  
59 coverage from June 20 to July 3 2021 in 20 countries: Australia ( $N=121$ ), France  
60 ( $N=788$ ), Germany ( $N=955$ ), Indonesia ( $N=97$ ), India ( $N=171$ ), Ireland ( $N=617$ ),  
61 Israel ( $N=333$ ), Italy ( $N=642$ ), Japan ( $N=105$ ), Mexico ( $N=368$ ), Netherland ( $N=456$ ),  
62 Norway ( $N=142$ ), Portugal ( $N=782$ ), Singapore ( $N=131$ ), Spain ( $N=689$ ),  
63 Switzerland ( $N=131$ ), Sweden ( $N=786$ ), Turkey ( $N=428$ ), United States ( $N=537$ ), and  
64 United Kingdom (UK,  $N=3534$ ) were collected from the Global Initiative on Sharing  
65 All Influenza Data (GISAID)[7].  $Mf$  was calculated as described previously [3]. We  
66 found that  $Mf$  was logarithmically reduced as the full vaccination rate increased in  
67 16 of the 20 countries ( $R^2=0.878$ , Figure 1A). To our knowledge, this is the first  
68 evidence that vaccinations successfully suppressed viral mutations. With 10.8%  
69 vaccinated rate,  $Mf$  was exceptionally low in Australia, likely as a result of the  
70 national lockdown restrictions. In contrast,  $Mf$  is higher in Japan, Switzerland, and  
71 United States, suggesting that their mitigation strategies have been less successful.  
72  
73 Previously we reported that *de novo* recombination of viral genome and positive  
74 selection pressure led to prevalent SARS-CoV-2 mutations among passengers in  
75 quarantine on the Diamond Princess cruise ship between January and March 2020  
76 [6]. It is still unknown whether COVID-19 variants are evolving randomly or under  
77 the selection pressure generated by mitigation efforts. We chronologically analyzed  
78 SARS-CoV-2 delta variant sequences in the UK ( $N=27,344$ ), India ( $N=4,451$ ) and

79 Australia ( $N=305$ ) from 13 February to 3 July 2021, respectively in the GISAID [7].  
80 Genome alignments and analysis using the Tajima  $D$  test, a neutrality statistic widely  
81 used in population genetics, were carried out as previously [6,8,9,10]. The Tajima  $D$   
82 test ( $D'$ ) compares pairwise nucleotide diversity ( $\pi$ , the average number of  
83 nucleotide differences per site between two sequences) and total polymorphism to  
84 infer selection and demographic events [6, 9, 10].  
85  
86 We observed that  $\pi$  was significantly lower in the UK ( $\pi < 1.5 \times 10^{-4}$ ) than others  
87 which emerged after April 24, 2021 ( $\pi > 2.0 \times 10^{-4}$ ;  $p < 0.01$ ) (Figure 1B), suggesting  
88 that the UK delta variants emerged with rapid clonal expansion, while others gained  
89 more singleton mutations.  $D'$  value decreased drastically in both the UK and India  
90 (Figure 1C). All variants eventually remained between -2.68 to -2.84 ( $p < 0.01$ ), which  
91 was similar to the  $D'$  value calculated from the alpha variant sequences in UK (-2.58  
92 to -2.78;  $N=15,396$ ) during the period of study. Negative  $D'$  signifies stronger  
93 demographic expansion or purifying (positive) selection, witnessed in both the UK  
94 and Indian variants<sup>10</sup>. In Australia,  $D'$  decreased in June 2021, suggesting positive  
95 selection exerted by lockdowns [6].  
96  
97 Together with available epidemiological reports [5], we found that one to three  
98 weeks after  $D'$  was reduced below -2.50, new COVID-19 outbreaks emerged in the  
99 UK and India (Figure 1C). Although drivers of positive selection may vary  
100 (vaccinations, lockdowns, etc.), we propose that a  $D'$  score with a threshold of -2.50  
101 is a promising forecasting tool for COVID-19 outbreaks. It is worth noting that  $D'$  of

102 the Australian delta variants reached -2.57 on 3 July 2021, suggesting that a further  
103 extension in restrictions was required to contain outbreaks due to low vaccination  
104 rates nationwide.

105

## 106 **Conclusion and recommendation**

107 More virulent strains of SARS-CoV-2 have emerged with enhanced transmissibility  
108 and immune evasion properties. For example, multiple variants have escaped  
109 neutralizing antibodies developed to target the spike protein receptor-binding or N-  
110 terminal domain [11]. What's more, the case numbers of breakthrough infection  
111 caused by the delta variant have increased drastically worldwide [12].

112

113 Our observations showed that countries with higher vaccination rates generated  
114 fewer mutations versus low vaccinated countries. This suggests that there is less of  
115 a chance for the virus to gain more virulent mutations in high vaccinated countries.  
116 It must be noted that the virus becomes more contagious as it is screened through  
117 the vaccinated population, eventually to become the dominant strain to infect the  
118 entire population. This is what we are seeing in the delta variant in the United  
119 States, the UK and many countries [12]. A negative effect of COVID-19 vaccination  
120 resistance could result in a large increase of virulent mutations and failure to reach  
121 herd immunity nationwide or globally.

122

123 Thus, we recommend that: 1) universal vaccination should be administered as soon  
124 as possible to suppress the generation of deadly mutations; 2) mitigations strategies

125 such as personal protection equipment, social distancing, etc., should be re-  
126 implemented with new urgency until full vaccination is reached in an effort to  
127 prevent viral transmission until the virus is eradicated; 3) genomic surveillance  
128 should be undertaken to monitor for new mutations; and 4) The Tajima  $D'$  threshold  
129 test further provides a tool by which we can forecast future outbreaks.

190 **Figure Legend**

191 Figure 1. (A) Correlation between full vaccinated rate [13] and mutation frequency  
192 ( $Mf$ ) from June 20 to July 3 2021 in 20 countries: Australia (AUS), France (FRA),  
193 Germany (GER), Indonesia (IDA), India (IND), Ireland (IRL), Israel (ISR), Italy (ITA),  
194 Japan (JPN), Mexico (MEX), Netherland (NED), Norway (NOR), Portugal (POR),  
195 Singapore (SGP), Spain (ESP), Switzerland (SUI), Sweden (SWE), Turkey (TUR),  
196 United States (USA), and UK. Logarithmic regression (solid) line was draw based on  
197 16 countries (pink dots) with a calculated 95% confidence interval (dashed lines).  
198 Japan, Switzerland, USA, and Australia are labeled in different colors as outliers. (B  
199 and C) Chronology of nucleotide diversity ( $\pi$ ) (B) and Tajima  $D'$  value (C) of SARS-  
200 CoV-2 delta variants in UK ( $N=27,344$ , blue), Indian ( $N=4,451$ , red), and Australian  
201 ( $N=305$ , green). Data were plotted every two weeks, and the data only represent  
202 the effective population size with more than 3 high quality sequences. The arrows  
203 label the epidemiological events of COVID-19 delta variants announced by the  
204 World Health Organization (WHO). WHO classified the delta variant as a global  
205 variant of interest (VOI) on 4 April 2021, and variants of concern (VOC) on 11 May  
206 2021 [5]. The dashed line in (C) labels the cut-off threshold -2.50 in Tajima  $D'$  test.
