

Supplemental Information

Supplemental Table 1: Methods and variables for multivariable modeling

	Original Analysis	Updated analysis
Variable Selection Method	...“demographic and medical history variables significantly associated with DMM community type in bivariate analysis ($p < 0.05$) and variables associated with MUI versus control and other variables of clinical significance” were selected as covariates.(1)	All clinical variables collected in the HMS-ESTEEM study(2, 3) were ranked [^] based on a <i>priori</i> knowledge of how each might be associated with microbial community type or MUI. Highest tier of ranked clinical variables were incorporated into multivariable models; certain variables without associations were removed to avoid overfitting models (i.e., avoid exceeding 15 degrees of freedom).
Clinical Variables		
Age	Included; due to associations between age and DMM communities, reduced models in age <51 and age >51 created	Included; reduced models not necessary as associations no longer remain when incorporating other covariates
Race*	Not included	Tier 1 variable evaluated in preliminary models; not included in final model (lack of association)
Ethnicity (Latina vs not Latina)*	Included	Included
BMI	Included	Included
Recurrent UTI (3 or more in prior year)*	Not included despite associations with MUI status in bivariate analysis	Included
Smoking Status (active vs not active)	Included	Included
Menopausal Status	Not included	Included as composite variable ^{&}
Hormone Status	Not included despite associations with MUI status in bivariate analysis	Included as composite variable ^{&}
Vaginal pH	Not included	Included
Number days since prior catheterization	Not included	Included ^{\$}

Technical
Variables

Clinical Site	Model "included a random effect for clinical site." ⁽¹⁾	Tier 2 variable included in preliminary models; removed from final model due to inconsistent associations and to avoid overfitting models.
Sample processing time	Not included	Not included [#]

DMM = Dirichlet multinomial mixture, HMS-ESTEEM = Human Microbiome Study in the Effects of Surgical Treatment Enhanced with Exercise for Mixed Urinary Incontinence randomized trial, MUI = mixed urinary incontinence, BMI = body mass index, UTI = urinary tract infection

[^]Variables ranked into three tiers with Tier 1 comprising 10 variables listed above with highest likelihood for having associations with urinary microbes and/or clinical condition. Tier 2 variables included parity, responses on validated questionnaires, clinical site, and presence of detrusor overactivity on urodynamic testing; Tier 3 variables were all others.

^{*}Based on patient self-report

[&]Menopausal status (e.g., premenopausal, postmenopausal, unknown) was collected but 17% responded as "unknown". Thus, this variable was not included in initial HMS-ESTEEM analysis. Upon detailed review, clinicians were able to resolve the "unknown" responses by considering 3 variables in context with each other: age, menopausal status, and use of estrogen hormone. Thus, a composite variable was derived that incorporates both menopausal & hormonal status with 3 potential responses: 1) postmenopausal, no hormones; 2) post-menopausal any hormones (oral, transdermal, vaginal); 3) premenopausal.

[§]Number of days since prior catheterization was assessed in preliminary models as both a continuous variable and as a categorical variable based on clinical assessment of the level of risk of modifying urinary microbial communities (<30 days; 30-90 days; >90 days).

[#]8 samples with prolonged processing time qualitatively explored. Samples were processed 4-6 days after collection due to weekend shipping (compared to within 2 days per study protocol). All were maintained and shipped with DNA protectant (Assay Assure™) and no differences were noted in data quality.

Supplemental Figure 1: Preliminary modeling results testing for associations with mixed urinary incontinence (MUI) versus control status. Models include data from DMM clustering as the microbial communities; filtering threshold of 0.00001. Fig 1A shows output from a preliminary model incorporating microbial communities and clinical site showing no associations with MUI; Fig 1B shows output from another preliminary model incorporating microbial communities, clinical site, and all clinical covariates with one site demonstrating an association with MUI status. The final model with microbial communities and clinical covariates (site removed) is depicted in Table 2. Similar patterns were noted in all models including those with DMM clusters and filtering threshold of 0.00005, as well as those with DTMM clusters at both filtering thresholds.

Supplemental Figure 2: Genera identified among paired samples. Each panel depicts the relative abundance of one genus. On the left is the relative abundance from the V1-V3 amplicon, connected by a line to the right, which shows the relative abundance in the same sample when identified from the V4-V6 amplicon. In each panel the black line summarizes the median abundances across all paired samples. The top 105 (based on abundance) genera are depicted.
