1 Abstract

2 Alcohol Use Disorder (AUD) is closely linked to the brain regions forming the neurocircuitry of
3 addiction. Postmortem human brain tissue enables the direct study of the molecular
4 pathomechanisms of AUD. This study aims to identify these mechanisms by examining
5 differential DNA-methylation between cases with severe AUD (n=53) and controls (n=58)
6 using a brain region-specific approach, in which sample sizes ranged between 46 and 94.
7 Samples of the anterior cingulate cortex (ACC), Brodmann Area 9 (BA9), caudate nucleus
8 (CN), ventral striatum (VS), and putamen (PUT) were investigated. DNA-methylation levels
9 were determined using the Illumina HumanMethylationEPIC Beadchip. Epigenome-wide
10 association analyses were carried out to identify differentially methylated CpG-sites and
11 regions between cases and controls in each brain region. Weighted Correlation Network
12 Analysis (WGCNA), gene-set and GWAS-enrichment analyses were performed. Two
13 differentially methylated CpG-sites were associated with AUD in the CN, and 18 in VS ($q <$
14 $.05$). No epigenome-wide significant CpG-sites were found in BA9, ACC, or PUT.
15 Differentially methylated regions associated with AUD case-/control status ($q <$ $.05$) were
16 found in the CN (n=6), VS (n=18) and ACC (n=1). In the VS, the WGCNA-module showing
17 the strongest association with AUD was enriched for immune-related pathways. This study is
18 the first to analyze methylation differences between AUD cases and controls in multiple brain
19 regions and consists of the largest sample to date. Several novel CpG-sites and regions
20 implicated in AUD were identified, providing a first basis to explore epigenetic correlates of
21 AUD.

1 Introduction

2 Every year, approximately 5.3% of all deaths worldwide are a result of the harmful use of
3 alcohol and approximately 230 diseases are associated with alcohol use [1]. The lifetime
4 prevalence of alcohol use disorder (AUD) varies globally, with North African/Middle Eastern
5 countries having the lowest (0.59%) and Eastern European countries the highest (4.25%)
6 prevalence. With a global prevalence of 1.32%, AUD is an important contributor to global
7 disease burden [2]. AUD is a moderately heritable disease; a meta-analysis of twin studies
8 estimated a heritability of 49% [3].

9 It has been proposed that drug-induced alterations in gene expression in the neurocircuitry of
10 the brain contribute to addiction [4]. Recent evidence suggests that alterations in DNA-
11 methylation, an epigenetic mechanism affecting gene expression, play an important role in
12 addiction (for reviews see: [5,6]). Differential DNA-methylation is associated with alcohol
13 consumption and AUD both in peripheral blood and postmortem brain tissue (for an overview
14 see: Wedemeyer, et al. ⁷). Examining alterations in DNA-methylation in epigenome-wide
15 association studies (EWAS) allows for the investigation of inter-individual differences which
16 are attributable to a phenotype [8]. For example, a recent EWAS of AUD in peripheral blood
17 suggests that networks in glucocorticoid signaling and inflammation-related genes are
18 associated with AUD [9].

19 Human postmortem brain tissue is a sparse and valuable resource and allows a more direct
20 characterization of AUD mechanisms than possible by analyzing peripheral blood [10]. So
21 far, a small number of postmortem brain studies have been conducted, mostly investigating
22 the prefrontal cortex (PFC), which, due to its role in reward regulation and higher-order
23 executive function, is thought to be disrupted in addiction [11]. An EWAS comparing
24 individuals with AUD with age-matched controls detected a range of differentially methylated
25 CpG-sites in Brodmann Area 9 (BA9) in 16 pairs of males, but not in seven pairs of females
26 [12]. Another study identified AUD-associated differentially methylated CpG-sites in
27 Brodmann Area 10, which did not remain significant after multiple testing correction [13].
28 However, downstream analyses implicated *NR3C1*, a gene coding for the glucocorticoid

1 receptor, which is crucial to stress regulation and found to be functionally relevant in AUD.
2 The increased DNA-methylation in individuals with AUD was also associated with reduced
3 *NR3C1* mRNA and protein expression levels [13].
4 Investigating DNA-methylation in the wider addiction neurocircuitry may give deeper insights
5 into the pathophysiological mechanisms of AUD, and may reveal potential targets for
6 treatment or prevention [14,15]. Dysfunction in the addiction neurocircuitry, which comprises
7 areas involved in cognitive control such as the dorsolateral PFC, the anterior cingulate cortex
8 (ACC), and regions in the basal ganglia, can have impairing consequences associated with
9 disrupted reward-related decision-making, alcohol craving, and compulsive alcohol
10 consumption [11,16]. Of particular interest is the striatum, which is divided into ventral and
11 dorsal subdivisions based on function and connectivity. The ventral striatum (VS), comprises
12 the nucleus accumbens (NAcc) and olfactory tubercle while the dorsal striatum contains the
13 caudate nucleus (CN) and putamen (PUT) [17]. The NAcc is thought to be important in
14 addiction due to its role in processing motivation, more precisely aversion and reward [17].
15 The caudate nucleus and putamen both influence motor function; in addition, the caudate is
16 involved in goal-directed action, executive functioning and cognitive control, while the
17 putamen is implicated in various types of learning, including reinforcement learning and habit
18 formation [18]. In a study investigating DNA-methylation in PFC and NAcc, CpG-sites in
19 *DLGAP2* emerged as differentially methylated between 39 male AUD cases and 47 controls
20 in both brain regions; the differences were genotype-dependent [19].
21 In the present study, we aimed to identify epigenetic mechanisms associated with AUD, in
22 five brain regions previously implicated in the neurocircuitry of addiction [17]. Brain-region
23 specific EWAS of AUD were performed in the BA9, ACC, VS, CN and PUT.

1 Materials and Methods

2 Samples

3 In total, 395 human postmortem brain samples from 111 subjects (53 AUD, 58 controls) were
4 obtained from the New South Wales Tissue Resource Center (University of Sydney,
5 Australia) under study reference number 2009-238N-MA by the Ethics Committee II of the
6 Medical Faculty Mannheim. AUD and control subjects were matched by age and sex. All
7 individuals met the following inclusion criteria, which were determined by next-of-kin
8 interviews: age >18, no history of severe psychiatric, neurodevelopmental, or other
9 substance use disorders (except nicotine use disorder), and Western European ancestry.
10 Individuals with AUD were classified according to DSM-IV criteria and had consumed at least
11 80g alcohol daily, whereas controls had consumed less than 20g. Methylation data was
12 generated in two batches and each batch was analyzed separately. The first batch
13 comprised 220 samples of BA9, ACC, CN, and VS from 28 cases and 27 controls. In the
14 second batch, 175 samples from 56 additional individuals from the CN, VS, and PUT were
15 analyzed. Material from one to five brain regions was available for each individual. Therefore,
16 the sample composition varies between the brain region-specific analyses. A sample
17 description can be found in Table 1. Table 2 shows the number of samples for each brain
18 region and each batch. Additional phenotype information, such as cause of death and
19 detailed exclusion criteria can be found in the Supplementary Information (Table S1 and Text
20 S1).

21 Epigenome-wide methylation

22 DNA was extracted from bulk brain tissue using the DNeasy extraction kit from Qiagen
23 (Qiagen, Hilden, Germany). The genomic DNA samples were stored at -20°C. For the
24 microarray analysis, the samples were randomized based on AUD case/control status and
25 sex, and pipetted on processing plates. Due to the sample and different group sizes,
26 samples from each brain region were processed on separate plates. Epigenome-wide

1 methylation levels were determined using the Illumina HumanMethylationEPIC Beadchip and
2 Illumina HiScan array scanning systems (Illumina, San Diego, CA).

Table 1.
Descriptive statistics of demographic data.

Characteristic	Cases	Controls	<i>p</i>
N	53	58	
Age, years	56.72 (10.81)	56.69 (10.29)	0.989
Sex (M/F)	34/19	40/18	0.737
pH-value	6.5 (0.28)	6.57 (0.32)	0.189
PMI (hours)	35.46 (16.1)	28.17 (15.29)	0.038*
Estimated Smoking	0.72 (0.26)	0.51 (0.31)	> .001*
Blood Alcohol level (N)	8	0	
Blood Alcohol Level (g/100ml)	0.211 (0.179)		
Number of Brain Regions			
	5 19 (35.8%)	19 (32.8%)	
	4 9 (17.0%)	8 (13.8%)	
	3 18 (34.0%)	21 (36.2%)	
	2 0 (0%)	3 (5.1%)	
	1 7 (13.2%)	7 (12.1%)	

Data are presented as count (n/n; n (%)) or mean (\pm SD), PMI: post-mortem interval, pH: pH-value of the brain, p: p-value of t-Test comparing cases and controls, estimated smoking is the likelihood of smoking estimated based on the methylation data.

**significant difference between cases and controls*

3
4 Data preprocessing, quality control, and filtering
5 All data preprocessing and analysis steps were performed using the R statistical
6 environment, version 3.6.1. An updated version of the CPACOR-pipeline published by
7 Lehne, et al.²⁰ was used to extract methylation data from raw intensity data and perform
8 quality control. Samples were removed if (i) DNA quality was not sufficient (missing rate >
9 0.10) or (ii) a discrepancy between methylation-based and phenotypic sex emerged. Probes
10 were removed when (i) the call-rate was insufficient (< 0.95), (ii) SNPs with a minor allele
11 frequency > 0.10 were located in the probe sequence, (iii) the probes were located on the X
12 or Y chromosome. After quality control 381 samples remained. Depending on the brain
13 region, 657 593 – 694 791 sites were available for analysis after filtering. Detailed

1 descriptions of sample size, the number of sites remaining after QC, and the inflation
2 coefficient lambda for each model can be found in Table 2.

3

Table 2.
Sample Overview.

Brain Region	Total N	Case		Control		# of CpG sites	Genomic Inflation
		Batch I	Batch II	Batch I	Batch II		
Anterior Cingulate Cortex	54	28		26		657 593	0.958
Brodmann Area 9	46	25		21		657 593	0.942
Putamen	94		44		50	694 572	0.963
Caudate Nucleus	94	28	17	27	22	694 790	0.919
Ventral Striatum	93	28	18	26	21	694 790	0.962

Number of individuals per brain region after quality control. # of CpG-sites refers to the number of sites remaining after quality control, for VS and CN union of the two batches.

4

5 Statistical Analysis

6 Methylation values were log-transformed (base 2) and included as dependent variables in
7 the association analyses, as recommended by Du, et al. ²¹. Control for batch effects and
8 technical quality was applied by extracting signals of the internal control probes of the EPIC
9 array, performing principal component analysis (PCA), and extracting the first ten principal
10 components. These were included as covariates in all association tests. To control for cell-
11 type heterogeneity, cell counts were estimated using the method by Houseman, et al. ²², with
12 the dorsolateral prefrontal cortex reference data [23]. This approach results in two estimates,
13 one for neurons and one for other cell types. These were standardized so that the sum of
14 both counts added up to one. The estimate for neurons was included as a covariate in all
15 analyses.

16 Data on smoking was not available for all participants (missing for n=11, 10.81%). Smoking

1 status was therefore estimated based on a validated set of sites [24]. Estimated smoking was
2 included as a continuous covariate. 86% of current smokers were correctly classified;
3 according to the regression model their likelihood of smoking was >50%.

4 *Epigenome-wide association analysis.* Tests of methylation differences between individuals
5 with AUD and control subjects were performed with linear models, adjusting for sex, age,
6 postmortem interval (PMI), pH-value, estimated smoking, standardized neuronal cell count,
7 and the first ten principal components of the internal control probes. Each region and each
8 batch was analyzed separately. The summary statistics for CN and VS were then meta-
9 analyzed based on effect estimates and standard errors using METAL [25]. P-values were
10 corrected for multiple testing using the Benjamini-Hochberg (FDR) correction [26]; resulting
11 values are reported as q -values. CpG-sites were annotated using the manufacturer's
12 manifest (<http://webdata.illumina.com.s3-website-us-east-1.amazonaws.com/downloads/productfiles/methylationEPIC/infinium-methylationepic-v-1-0-b4-manifest-file-csv.zip>; downloaded on 10th of August 2018). Regression coefficients of
13 differential methylation for the epigenome-wide significant CpG-sites were summarized for
14 each brain region. As each brain region was processed on a separate plate, no inferential
15 statistical procedure was applied to compare DNA-methylation levels between brain regions
16 (due to confounding of batch and regions). Test statistics from all epigenome-wide significant
17 CpG-sites were reported for each brain region and also for an independent EWAS in
18 peripheral blood, in which DNA-methylation levels of male patients with AUD, who had just
19 entered withdrawal treatment were compared with healthy controls [27]. As the cause of
20 death of two control subjects from the second batch was "toxicity", a sensitivity analysis
21 excluding these subjects was performed in CN, VS, and PUT.

24 *Differentially methylated regions (DMRs).* DMRs were identified using the comb-p algorithm
25 [28], which accounts for autocorrelation between tests of adjacent methylation sites and
26 combines these sites to regions of enrichment, in a given window. The following settings
27 were used: Seed-p value < 0.01, minimum of 2 probes, sliding window 500 bp. The Šidák

1 correction as implemented in comb-p was applied to correct for multiple testing. Comb-p was
2 applied to the result statistics for all brain regions.

3 *Pyrosequencing and TaqMan Assay*. The DMR in *DDAH2* was replicated by pyrosequencing
4 and gene expression levels were determined using a TaqMan Assay (for details see
5 Supplementary Text S3).

6 *Gene-Ontology (GO) over-representation analysis*. Functional analysis to identify gene
7 pathways targeted by differentially methylated CpG-sites was performed for sites with a
8 threshold of $p_{nominal} < 0.001$ using missMethyl [29]. missMethyl controls for probe number
9 bias, the increased likelihood of a gene to be differentially methylated, if more probes cover
10 the gene and multi-gene bias, and the fact that probes can be annotated to more than one
11 gene.

12 *GWAS-Enrichment-Analysis*. Gene-sets were created consisting of the genes to which the
13 differentially methylated CpG-sites were annotated. Two gene-sets were created for each of
14 the CN and VS results, one for genes implicated by epigenome-wide significant CpG-sites,
15 and one for genes implicated by nominally significant CpG-sites, giving a total of four gene-
16 sets. Multi-marker Analysis of GenoMic Annotation (MAGMA)[30] was used to test
17 enrichment of those gene-sets in the results of a genome-wide association study (GWAS) of
18 AUD [31].

19 *Weighted Correlation Network Analysis (WGCNA)*. The WGCNA R package [32] was used to
20 generate co-methylated modules and relate those to AUD case-/control status. For each
21 brain region the quantile-normalized beta values of CpG-sites nominally associated ($p <$
22 0.05) with AUD status were used as input. Soft power thresholds were picked according to
23 the criterion of approximate scale-free topology ($R_{signed}^2 > 0.90$). The number of CpG-sites
24 and the soft power thresholds picked can be found in Supplementary Table S2. Unassigned
25 CpG-sites were clustered in the “grey” module, which was not taken into account for further
26 analyses. For each brain region, the module of correlated CpG-sites with the highest

1 association with AUD was identified. A GO analysis with the CpG-sites comprising the
2 module was performed using missMethyl [29].

3 GWAS ATLAS. The PheWAS tool from the publicly available database GWAS ATLAS [33]
4 [<https://atlas.ctglab.nl/>] was used to identify genome-wide significant associations of the
5 genes implied by the top hits in the EWAS.

6

7 Results

8 *Epigenome-wide association Analysis.* In the CN, two CpG-sites were epigenome-wide
9 significantly hypomethylated in AUD cases compared to controls. The two sites were
10 annotated to the genes *IREB2* (cg04214706) and *HMGCR* (cg26685658). cg04214706 was
11 also differentially methylated in the ACC ($p_{nominal} = 0.005$).

12 In the VS, 18 CpG-sites were epigenome-wide significantly associated with AUD. Nine CpG-
13 sites were hyper- and nine hypomethylated. The top three hits were annotated to *SLC30A8*,
14 *FAM20B*, and *PCAT29*. Of the epigenome-wide significant CpG-sites, cg12049992 in
15 *PIEZO2* and cg16767842 in *GLANT9* were also differentially methylated in CN ($p_{nominal} \leq$
16 0.023). Additionally, cg1354575 in *TCL1A* was differentially methylated in PUT ($p_{nominal} =$
17 0.035) and cg02849689 (intergenic) in ACC ($p_{nominal} = 0.012$). Three of the epigenome-wide
18 significant CpG-sites showed nominally significant associations in an EWAS of AUD in
19 peripheral blood, namely cg27512762 in *PCAT29*, cg06427508 in *KLHL6* (effect in opposite
20 direction), and cg02849689, which was not annotated to a nearby gene. In ACC, BA9, and
21 PUT no epigenome-wide significant differentially methylated CpG-sites were identified ($q \geq$
22 0.57). Epigenome-wide significant CpG-sites can be found in Table 3 and the top 100
23 associations for each brain region, together with more detailed information on location and
24 annotation to enhancers, in supplementary tables (S3a–S3e). All coefficients of CpG-sites
25 with $q < 0.05$ for each brain region and in peripheral blood are summarized in Supplementary
26 Table S4. Manhattan plots for EWAS in the ACC, CN, and VS are depicted in Figure 1.
27 Post-hoc power analyses using the web app EPIC Array Power Calculations

1 (<https://epigenetics.essex.ac.uk/shiny/EPICDNAMPowerCalcs/>) were conducted for sample
2 sizes of $n=46$ and $n=94$, to adequately reflect our sample sizes and the additional settings
3 2% mean difference and significance threshold 1×10^{-7} , which was closest to the FDR
4 corrected thresholds in the present study. This resulted in 11% of CpG-sites having a power
5 larger than 90% to detect mean methylation differences of 2% for a sample size of 94 and
6 3.18% for a sample size of 46 (see also Supplementary Figure S1). It has to be noted, that
7 the power calculations assumed equal distributions between cases and controls, which was
8 not the case for all analyses. The sensitivity analyses did not reveal major differences
9 between the EWAS in the complete sample and the reduced sample, in which control
10 subjects who died of toxicity were excluded. The effect sizes of the nominally significant
11 CpG-sites in each of the brain regions were highly correlated ($r_{CN} = 0.99$, $r_{VS} = 0.98$, $r_{PUT} =$
12 0.99 , all $p < 0.001$). Scatterplots of the effect sizes for nominally significant CpG-sites in both
13 analyses are depicted in Supplementary Figure S2.

14 *Differentially methylated regions.* In the CN, 10 DMRs were associated with AUD. The top
15 three regions were annotated to the genes *DDAH2*, *CCDC152*, and *CAMSAP1*. Six DMRs
16 were associated with AUD ($q < 0.05$) in the VS, with the three most strongly associated
17 regions in *TMEM232*, *FANCD2OS*, and *HM13*. All significant DMRs for CN and VS are
18 highlighted in figure 1 and can be found in supplementary tables S5a and S5b. In the ACC,
19 one region in *HLA9* was differentially methylated ($p_{\text{Šidák-corrected}} = 3.25 \times 10^{-6}$). No epigenome-
20 wide significant DMRs were observed in BA9 and PUT.

21 The DMR in *DDAH2* was replicated by pyrosequencing (cg04074004: $t(76.77) = 2.39$, $p =$
22 0.019). Differential expression was not observed (all $p > 0.136$). For details see
23 Supplementary Text S3.

24 *Gene-Ontology Analysis.* The strongest overrepresentation in the CN was for the biological
25 process “homophilic cell adhesion via plasma membrane adhesion molecules” ($p = 5.37 \times 10^{-6}$,
26 $q = 0.12$) and “cell-cell adhesion via plasma-membrane adhesion molecules” ($p = 1.68 \times 10^{-5}$,
27 $q = 0.187$). In the VS, the cellular “Lsm1-7-Pat1 complex” showed the strongest
28 overrepresentation ($p = 6.49 \times 10^{-5}$, $q \approx 1$). Both associations did not remain significant after

1 correction for multiple testing. The ten GO-terms showing the strongest overrepresentation
2 can be found in Supplementary Tables S6a and S6b.

3 *GWAS enrichment analysis*. No significant enrichment was observed in any of the regions
4 and gene-sets tested (all $p \geq 0.277$).

5 *Weighted Correlation Network Analysis (WGCNA)*. For the caudate nucleus, 15 modules
6 were identified consisting of 49-10,330 CpG-sites (*Median* = 965). The strongest association
7 with AUD was observed for module “black”, which showed the strongest enrichment for the
8 cellular component “PML body” ($p = 0.001$) and the molecular function “G-rich strand
9 telomeric DNA binding” ($p = 0.001$). For CpG-sites nominally associated with AUD status in
10 the VS 14 modules were identified, consisting of 38-12,721 CpG-sites (*Median* = 611).
11 Module “purple” showed the strongest association with AUD and was enriched for a variety
12 of immune-related GO-terms, such as the biological processes “regulation of T-cell
13 proliferation” ($p = 4.32e^{-6}$) and “regulation of leukocyte cell-cell adhesion” ($p = 6.83e^{-6}$). For
14 caudate nucleus module “black” and ventral striatum module “purple” the correlations of the
15 gene significance (GS), which reflects the biological significance of a CpG-site with an
16 external trait (here AUD) and the module membership (MM), which reflects the correlation of
17 each CpG-site with the module, were calculated and are displayed in Figure 2a and 2b. The
18 top enriched GO-terms for these modules can be found in Supplementary Tables S7a and
19 S7b. Results for ACC, BA9, and putamen are described in the Supplementary Information
20 (Text S2, Figure S3).

3 cingulate cortex; (B) caudate nucleus; (C) ventral striatum. Highlighted CpG-sites represent
4 differentially methylated regions. Genes implicated by CpGs (light and dark grey) and DMRs
5 (green) are specified in the figures. Red line indicates FDR-corrected significance.

1
2 Figure 2. Association of gene significance for AUD status with module membership, for the
3 modules A) “black” in caudate nucleus, and B) “purple” in ventral striatum.

4
5 *GWAS ATLAS*. *GWAS ATLAS* results for the genes implicated by the most strongly
6 associated site and region both in the CN and VS can be found in Supplementary Tables
7 S8a-S8d. In brief, *IREB2* has previously been associated with smoking phenotypes (e.g.,
8 number of cigarettes a day, numbers of cigarettes previously smoked daily), parental
9 illnesses such as lung cancer and chronic bronchitis, and psychiatric disorders like
10 schizophrenia and bipolar disorder [33-35]. Genome-wide significant associations of *DDAH2*
11 with phenotypes from a variety of domains, e.g., immunological, metabolic, respiratory, and
12 psychiatric have been found. In the psychiatric domain, *DDAH2* has been associated with
13 schizophrenia and bipolar disorder e.g. [34,36]. *SLC30A8* has been implied in blood sugar
14 levels [37] and *TMEM232* in allergic rhinitis and asthma [33].

15

1 Discussion

2 The present study examined DNA-methylation associated with AUD in regions of the
3 addiction neurocircuitry using an epigenome-wide methylation analysis approach employed
4 in human postmortem brain tissue. The largest of its kind to date and first to examine five
5 brain regions, this study identified several novel differentially methylated CpG-sites as well as
6 DMRs associated with AUD, providing potential insight into underlying mechanisms.

7 We found significant differentially methylated CpG-sites in two striatal regions. In the caudate
8 nucleus, two epigenome-wide significant CpG-sites in *IREB2* and *HMGCR*, were identified.
9 *IREB2* is a gene encoding iron regulatory protein 2, which is an RNA-binding protein that is
10 involved in the regulation of cellular iron metabolism [[https://www.genecards.org/cgi-](https://www.genecards.org/cgi-bin/carddisp.pl?gene=IREB2)
11 [bin/carddisp.pl?gene=IREB2](https://www.genecards.org/cgi-bin/carddisp.pl?gene=IREB2)]. Iron overload in the brain has previously been associated with
12 cognitive decline in AUD [38]. Neurodegeneration has been reported in two subjects with bi-
13 allelic loss of function variants in *IREB2* [39,40]. *IREB2* has also been associated with
14 smoking phenotypes [33]. The association with smoking, which strongly affects DNA
15 methylation [41,42], may be linked to the relevance of the gene to addiction phenotypes. In
16 the present study, the *IREB2*-CpG-site was also differentially methylated in the anterior
17 cingulate cortex (nominal significance), which might reflect a relevance in addiction
18 phenotypes in multiple brain regions.

19 In the ventral striatum, 18 CpG-sites were epigenome-wide significantly associated with
20 AUD. The strongest association was observed in a CpG-site in *SLC30A8*, which encodes a
21 zinc efflux transporter that is involved in the accumulation of zinc in the intracellular vesicles.
22 Zinc is a structure-building element in alcohol dehydrogenase (ADH) and thereby important
23 for the proper function of ADH, which is needed to break down alcohol [43]. Differential
24 methylation in *SCL30A8* may lead to altered Zinc availability and indirectly impact ADH
25 function, and thus alcohol metabolism. *SLC30A8* has also been implicated in type 1 and type
26 2 diabetes [44]. In both types epigenetic and transcriptomic levels of *SLC30A8* have shown
27 to be altered [45]. Heavy alcohol consumption is also an established risk factor for type 2

1 diabetes on the phenotypic level [46]. Three of the epigenome-wide significant CpG-sites
2 were also previously differentially methylated in an independent EWAS of AUD [27]; these
3 convergent results might point towards a cross-tissue effect of these sites.

4 Significant regional methylation differences were observed in the anterior cingulate cortex,
5 caudate nucleus, and ventral striatum. One differentially methylated region was observed in
6 the anterior cingulate cortex and that region was annotated to HLA complex group 9, a non-
7 coding RNA in the major histocompatibility complex (MHC). HLA antigens play a role in AUD
8 and alcohol-associated liver disease [47]. In the caudate nucleus, the DMR showing the
9 strongest association with AUD was annotated to *DDAH2*, encoding for dimethylarginine
10 dimethylaminohydrolase, which is involved in the formation of nitric oxide by indirect
11 inhibition of nitric oxide synthase (NOS) [[https://www.genecards.org/cgi-](https://www.genecards.org/cgi-bin/carddisp.pl?gene=DDAH2)
12 [bin/carddisp.pl?gene=DDAH2](https://www.genecards.org/cgi-bin/carddisp.pl?gene=DDAH2)]. Nitric oxide has previously been associated with sleep
13 disturbances, as part of the sleep-wake state controlling metabolites [48]. Sleep disorders
14 and disturbances, such as decreased total sleep time and decreased sleep efficiency, are
15 common in individuals during periods of alcohol consumption and prolonged withdrawal
16 [49,50]. In rodent studies, alcohol exposure influenced NOS expression in the brain [51] and
17 the knockout of neuronal NOS was associated with increased consumption of highly
18 concentrated alcohol solutions [52]. Although the DMR in *DDAH2* was replicated by
19 pyrosequencing, we did not observe differential gene expression between AUD cases and
20 controls. It has to be noted, that differential gene expression is only partly explained by DNA-
21 methylation differences. For example, in postmortem brain samples of individuals with
22 schizophrenia and controls, 204 of 71,753 tested CpG gene pairs were significantly
23 correlated [53]. A potential functional relevance of the DMR in *DDAH2* requires further
24 investigation, for instance in relation to contact frequency maps (chromosomal
25 architecture/Hi-C), which can be simultaneously studied with the methylome in single-cell
26 experiments [54].

1 Of the six DMRs identified in the ventral striatum, a region in *TMEM232* showed the
2 strongest association. *TMEM232* has previously been associated with respiratory traits, such
3 as seasonal allergic rhinitis [55]. Another significant CpG-site was annotated to *HM13*. This
4 gene encodes for minor histocompatibility antigen H13. In general, minor histocompatibility
5 antigens function in the immune system by recognizing T cells [56]. No studies have
6 investigated direct associations between AUD and H13 expression changes yet, but it is
7 known that the immune system is downregulated in patients with AUD [57].

8 GO-term analyses investigating molecular functions associated with differentially methylated
9 CpG-sites did not yield significant results after multiple testing correction, which is most likely
10 attributable to the limited statistical power. No significant enrichment was observed for each
11 of the gene-sets in GWAS signals for AUD, which could indicate that differential methylation
12 in the newly identified CpG-sites is more sensitive to environmental factors than genetic
13 effects.

14 In the WGCNA analysis in VS a module enriched for immune-processes was most strongly
15 associated with AUD, which are known to be influenced by alcohol abuse [58].

16 In this brain region-specific analysis, comparing individuals with AUD and controls, we
17 focused beside prefrontal areas on striatal regions, as previous studies have indicated that
18 AUD may be associated with a striatal shift in activation from ventral to dorsal, as drug intake
19 changes from goal-directed to habitual [59,60]. These studies focus on changes in
20 neurotransmitter release and functional connectivity but it is not known how epigenetic
21 changes impact this functional striatal shift. Our epigenome-wide results provide a first basis
22 to explore epigenetic contributions to functional striatal changes.

23 This study has several limitations. The first is PMI, which can influence the tissue quality. The
24 longer the individual has been deceased before the tissue was extracted from the body, the
25 further along are degradation processes [61]. While we corrected for this in our analyses our
26 results may have been affected by postmortem degradation processes nevertheless.
27 Second, we cannot infer whether the observed differences in DNA-methylation are a result of

1 addiction or long-term alcohol consumption, which affects multiple organ systems. Third, the
2 methylation array used in the present study combined with the bisulfite conversion does not
3 distinguish between methylation and hydroxymethylation. Therefore, no conclusions can be
4 drawn regarding methylation type specific effects. Also, for several CpG-sites the effect in the
5 meta-analysis was driven by a large effect in one, but not the other batch and in some of the
6 cases this went hand-in-hand with a change in direction. For example, cg04214706 had a
7 small positive effect, which was statistically not different from zero in the first batch, and a
8 large negative effect in the second. Further samples are needed to validate these findings.
9 Due to the sparse availability of human postmortem brain tissue, our sample size is small
10 compared to EWAS in peripheral blood, which results in limited statistical power, especially
11 taking into account the high multiple testing correction burden. However, EWAS analysis of
12 peripheral blood allows to reveal only limited conclusions about differential methylation in the
13 brain, whereas studies that examine multiple brain sites in a comparative fashion point to
14 region-specific functional changes. Lastly, the correlational design of this analysis does not
15 allow conclusions about the causality of the findings. DNA-methylation differences both be a
16 result of AUD and be present in individuals before onset of the disorder.

17 Here, we identified novel associations of differential DNA-methylation between AUD cases
18 and controls, which are prominent in alcohol-related pathways and diseases linked with AUD.
19 To confirm these observations, larger samples are needed from the respective brain regions.
20 Human postmortem brain tissue is difficult to obtain and very few brain banks focus on
21 substance use disorders. Combining existing datasets, generating a larger amount of DNA-
22 methylation data, and integrating multi-omics data, could lead to more conclusive results that
23 may help to understand the molecular changes due to substance abuse in the brain and
24 eventually to the identification of drug targets for more effective treatment of substance use
25 disorders.

1 Funding and Disclosures

2 The study was supported by the German Federal Ministry of Education and Research
3 (BMBF), “A systems-medicine approach towards distinct and shared resilience and
4 pathological mechanisms of substance use disorders“ (01ZX01909 to Rainer Spanagel,
5 Marcella Rietschel, Stephanie H Witt, Anita C Hansson), “Towards Targeted Oxytocin
6 Treatment in Alcohol Addiction (Target-OXY)” (031L0190A to Jerome C Foo). ERA-NET
7 program: Psi-Alc (FKZ: 01EW1908), and the Deutsche Forschungsgemeinschaft (DFG,
8 German Research Foundation) – Project-ID 402170461 – TRR 265 to Rainer Spanagel,
9 Anita C Hansson and Marcella Rietschel [62]
10 The authors have nothing to disclose.

11 Acknowledgments

12 We thank Elisabeth Röbel and Claudia Schäfer-Arnold for technical assistance.
13 Tissues were received from the New South Wales Brain Tissue Resource Centre at the
14 University of Sydney which is supported by the University of Sydney. Research reported in
15 this publication was supported by the National Institute of Alcohol Abuse and Alcoholism of
16 the National Institutes of Health under Award Number R28AA012725. The content is solely
17 the responsibility of the authors and does not represent the official views of the National
18 Institutes of Health.

19 Author Contributions

20 SHW, MR, RS, MMN, and ACH planned the investigation. MMF and ACH performed the
21 DNA and RNA extraction and SHH, PH, FD and MMN were responsible for generating
22 genome-wide methylation data. LZ, JF, JCF and FS developed the analysis plan. LZ and JF
23 performed all statistical analyses. HD, ACH and MMF performed replication and validation
24 experiments. LZ, MMF, JCF, LS, MR, FS, and SHW reviewed the literature for the paper. LZ,
25 MMF, FS and SHW drafted the manuscript. All authors contributed, revised, and edited the

- 1 final manuscript critically. All authors agreed to the publication of the final version of the
- 2 manuscript.
