2. Spreadsheet with final 252 reports included (separate spreadsheet)

3. Methods and weights used for the Stratified Weighted average Sum (SWS) approach:

We constructed a Stratified Weighted average Sum (SWS) by assigning weights at (a) Datasets, and (b) Imaging modality levels which is outlined below.

Working principle of Stratified Weighted average Sum (SWS): It is defined as $SWS := (\text{Dataset_weight}) * (\text{Img_modality_weight}) * (\text{Avg_AUC})$; where (i) Dataset_weight is number of studies used a specific type of datasets/Total number of studies (table(a)), (ii) Img_modality_weight is number of studies used subtypes within each dataset type/Total number of studies (table(b)), and (iii) Avg_AUC is average of AUC estimates found after doing stratification of imaging modality data.

The calculated variance of AUC estimates on a specific type of datasets is lower compared to variance of AUC estimations on unsegregated datasets. The variance decreases further when calculated on imaging modality (subtypes within each dataset type). Which means that SWS not only reduces the heterogeneity factor involved in the AUC estimation but also weights the AUC estimates based on the number of studies used which type of dataset and modality.

Note: If SWS matrix is not sparse then SWS AUC value will be close to Avg_AUC otherwise less/very less than Avg_AUC for a sparse/very sparse SWS matrix. Moreover the sparsity also tells us that the studies were mostly focused on which type/subtype of data and which ones were ignored completely.

Table(a)

| Dataset | n | Weight |
|---------------|-----|-----------|
| Only ADNI | 163 | 0.649402 |
| Local data | 57 | 0.227092 |
| ADNI + Others | 15 | 0.059761 |
