Abstract

Patients with chronic kidney disease (CKD) are at higher risk for coronavirus disease 2019 (COVID-19)-related morbidity and mortality. However, a significant portion of CKD patients showed hesitation toward vaccination in telephone survey of our center. Yet no serial data available on humoral response in patients with CKD, especially those on immunosuppression. We conducted a pilot, prospective study to survey the safety and humoral response to inactivated SARS-CoV-2 vaccine in CKD patients receiving a 2-dose immunization of inactivated SARS-CoV-2 vaccine. We found the neutralizing antibody titers in CKD patients was significantly lower than that in healthy controls, hypertension patients, and diabetes patients. Notably, immunosuppressive medication rather than eGFR levels or disease types showed effect on the reduction of immunogenicity. Interestingly, a third dose significantly boosted neutralizing antibody in CKD patients while immunosuppressants impeded the boosting effects. In conclusion, our data demonstrates that CKD patients, even for those on immunosuppression treatment, can benefit from a third vaccination boost by improving their humoral immunity.

Patients with chronic kidney disease (CKD) are at higher risk for coronavirus disease 2019 (COVID-19)-related morbidity and mortality than general populations and, early vaccination should be prioritized for this vulnerable population. However, concerning safety and efficacy, a significant portion of CKD patients (1720/2509, 68.6%) showed hesitation toward vaccination in telephone survey of our center (**Supplementary Figure 1**). Previous studies focused on exploring immune responses to COVID-19 vaccine in patients on dialysis or receiving kidney transplant^{1,2}. Yet no serial data available on humoral response in patients with CKD, especially those on immunosuppression³.

We conducted a pilot, prospective study to survey the safety and humoral response to inactivated SARS-CoV-2 vaccine in CKD patients receiving a 2-dose immunization of inactivated SARS-CoV-2 vaccine (**Supplementary Methods and Supplementary Figure 2**). Baseline characteristics of the participants are described in **Supplementary Table 1**. Briefly, the average age of CKD patients are 42.4 years with 20 (44%) females. 21 of them received SinoVac, 20 received Sinopharm and 4 received both sequentially. The most common form of CKD was chronic glomerulonephritis (27/45, 60.0%) followed by podocytopathy (5/45, 11.1%) and metabolic kidney disease (5/45, 11.1%). There were 18 patients taking immunosuppressants during the vaccination period with 17 (94.4%) receiving monotherapy. We tightly controlled age, female ratio, types of administered vaccines and sampling time across groups, except that the average age of diabetes patients is significantly older than CKD patients. None of these participants reported severe adverse effects after vaccination.

Using neutralizing antibody titer of 2 as seroconversion cutoff, we found 84% (38 of 45) of CKD patients seropositive, which was lower than that in healthy controls (98%), hypertension patients (98%) and diabetes patients (95%). The median neutralizing antibody titers in CKD patients was 6.29 (IQR, 2.78-14.62), which was significantly lower than that in healthy controls [8.91 (IQR, 6.14-16.01), $P = 5.15 \times 10^{-3}$], hypertension patients [8.66 (IQR, 5.24-15.68), $P = 0.02$], and diabetes patients [9.14 (IQR, 4.62-16.22), $P = 0.04$] (**Figure 1a**). Conversely, we did not

observe SARS-CoV-2-specific IgG or IgM differences between CKD patients and controls (**Figure 1 b-c**), despite of strong association between neutralizing antibody and SARS-CoV-2-specific IgG levels (**Supplementary Figure 3**). To better understand the immunogenicity of inactivated SARS-CoV-2 vaccine in CKD patients, we further stratified CKD patients into subgroups according to their disease diagnosis, eGFR levels and medication status (receiving immunosuppressants or not). Notably, immunosuppressive medication (**Figure 1d**) rather than eGFR levels (**Figure 1e**) or disease types (**Supplementary Figure 4**) showed effect on the reduction of immunogenicity. There were only 72.2% (13/18) of CKD patients receiving immunosuppressants tested seropositive after 2-dose vaccination. Moreover, we observed an immunosuppressant--dependent association between neutralizing antibody level and eGFR after adjusting for age and gender ($r = 0.627$, $P = 0.02$), suggesting that immunosuppressive agents could sensitize neutralizing antibody response to kidney function in non-dialysis kidney patients. Interestingly, a third dose significantly boosted neutralizing antibody in CKD patients while immunosuppressants impeded the boosting effects (**Supplementary Table 2** and **Supplementary Figure 5**).

Our initial analysis showed that majority (84%) of CKD patients acquired detectable neutralizing antibody against SARS-CoV-2 without severe adverse effects, while the antibody titers were lower than controls. In contrast, we did not observe such difference in SARS-CoV-2-specific IgG or IgM. The deviance between neutralizing antibody and SARS-CoV-2-specific IgG responses in CKD patients indicates that neutralizing antibody rather than IgG might be the most important marker reflecting humoral immune response in CKD patients. Subgroup analyses showed that immunosuppressive therapies rather than eGFR levels or disease diagnosis impair SARS-CoV-2 vaccine-induced immunity. Our analysis in non-dialysis kidney disease patients greatly supplemented previous studies on immunosuppressive therapies^{4,5} and dialysis^{6,7} impaired vaccine responses. We found that taking immunosuppressants hampers neutralizing antibody response in CKD patients and sensitizes neutralizing antibody response to kidney function. Additionally,

our data demonstrates that CKD patients, even for those on immunosuppression treatment, can benefit from a third vaccination boost by improving their humoral immunity.

ACKNOWLEDGMENTS

The authors thank the study participants, and clinical staff and nurses who providing help for their participation and sampling.
