1 Abstract

2 **Objectives:** To examine the relationship between socioeconomic factors and
3 unemployment among workers during COVID-19 pandemic in Japan.

4 **Design:** A prospective cohort study, follow-up from December 22–25, 2020 through
5 February 18–19, 2021.

6 **Setting:** The panelists registered with an Internet survey company

7 **Participants:** A cluster random sample of 33,087 workers with stratification by sex, job
8 type, and region among Japan's working population

9 **Main outcomes and measures:** Unemployment between December 2020 and February
10 2021

11 **Results:** Among the 19,941 participants, 725 (3.6%) had experienced unemployment.
12 Multivariate analysis showed that the significant high unemployment for women
13 (compared to men); younger age (compared to older age); being married (spouse not
14 working), bereaved or divorced, and unmarried (compared to married (spouse working));
15 annual household income less than 6 million yen, (compared to more than 10 million yen);
16 junior high or high school, vocational school, junior college, or technical school (compared
17 to graduate school); and temporary or contract employees, self-employed, agriculture,
18 forestry, or fishing (compared to general employees).

19 **Conclusions:** COVID-19 appears to have created difficulties for the vulnerable groups.

20 This suggests the need for employment and economic support for such individuals.

21

22 **Keywords:** socioeconomic factors; unemployment; vulnerable workers; COVID-19; Japan

23

24 **Strengths and limitations of this study**

25 Under the pandemic of COVID-19, we found that unemployment was associated

26 with socioeconomic factors such as age, sex, marriage, income, education and occupation.

27 Our findings suggest that in the event of a major epidemic, resulting in

28 unemployment among vulnerable segments of the labour market, regardless of whether

29 workers themselves are infected.

30 It was unclear why the participants had experienced unemployment

31 This study was conducted as an Internet survey, so the generalizability of our results

32 is limited.

40 **Introduction**

41 Unemployment is associated with a substantial risk of poor physical and mental health. It
 42 has consistently been shown to be significantly associated with increases in chronic heart
 43 disease, acute myocardial infarction, poor mental health, mental disorders,
 44 substance-related disorders, and suicide [1-3]. Unemployment is an important factor with
 45 regard to public health: it poses a health risk for individuals; it also leads to family poverty
 46 and, ultimately, constitutes a burden on social security.

47 COVID-19 has spread around the world and continues to exert a profound impact
 48 on global economies. Economic activities have changed drastically as a result: people have
 49 refrained from travel and outside eating, drinking, entertainment; they are encouraged to
 50 stay at home. The resulting unemployment has become a major concern: according to the
 51 Organization for Economic Co-operation and Development (OECD), countries'
 52 unemployment rates rose significantly around the same time as the outbreak of COVID-19
 53 [4]. In this regard, Japan's unemployment rate appears to have remained relatively
 54 low—around 3%. However, Official data on the unemployment rate may be
 55 underestimated, as it is defined as "people looking for work. Actually, data for Japan
 56 clearly show a marked decline in the number of people in employment and a fall in
 57 household income [5,6].

58 With disasters and crises in the past, the risk of unemployment was found to be
59 particularly high among socially vulnerable groups [7]. The OECD has identified young
60 people, women, middle-aged and older individuals, and migrants as vulnerable groups in
61 the labor market [8]. Those workers are also reported to be more likely to leave the labor
62 force owing to unemployment, disability, or economic inactivity [9]. By contrast, civil
63 servants, teachers, and employees of non-profit organizations in Japan have been found to
64 have lower turnover rates and greater job security [10].

65 It is assumed that individual socioeconomic status is still significantly associated
66 with unemployment during COVID-19. A cross-sectional study conducted in the United
67 States examined adverse outcomes associated with COVID-19 and the country's stay-home
68 policies. It found that African Americans, Hispanics, women, and low-income households
69 were more likely to experience unemployment, food insecurity, mental health problems,
70 poor access to health care, and rent or mortgage delinquency [11]. However, the
71 relationship between unemployment and socioeconomic status among Japanese during
72 COVID-19 is unclear. The present investigation was a cohort study of the relationship
73 between socioeconomic status and unemployment during COVID-19 among workers in
74 Japan.

75

76

78

79

80 **Methods**

81 This prospective cohort study about COVID-19 among Japanese workers was conducted
82 under the Collaborative Online Research on the Novel-coronavirus and Work
83 (CORoNaWork) Project. Details of the study protocol are described elsewhere [12]. Briefly,
84 we administered a baseline questionnaire on December 22–25, 2020 and a follow-up
85 questionnaire on February 18–19, 2021, when Japan was in its third pandemic wave.

86 For the baseline survey, we recruited 33,087 workers throughout Japan from
87 605,381 randomly selected panelists registered with an Internet survey company. The
88 inclusion criteria for participants were being currently employed and aged 20–65 years.
89 This study excluded health-care professionals and caregivers. We applied cluster sampling
90 with stratification by sex, job type, and region. We excluded 6051 invalid responses owing
91 to the following: response time <6 minutes; body weight <30 kg; height <140 cm;
92 inconsistent answers to similar questions; and incorrect answers to questions intended to
93 identify fraudulent responses. We distributed the follow-up questionnaire to the 27,036
94 people with valid responses to the baseline questionnaire. In total, 19,941 participants
95 completed both questionnaires (follow-up rate, 73.8%).

This study was approved by the Ethics Committee of the University of Occupational and Environmental Health, Japan (reference nos. R2-079 and R3-006). Informed consent was obtained from all participants.

Baseline characteristics

We retrieved the following data from the baseline survey for inclusion as explanatory variables: age; sex; marital status; socioeconomic status (based on annual household income and education); occupation; and job type. We categorized age into the following five groups: 20–29; 30–39; 40–49; 50–59; and ≥ 60 years. Marital status was classified into four groups: married (working spouse); married (spouse not working); divorced or widowed; and never married. Annual household income was classified into the following six groups: under 2 million; 2–4 million; 4–6 million; 6–8 million; 8–10 million; and >10 million yen. We categorized education into five groups: up to junior high school; up to high school; up to junior college or technical school; up to university; and graduate school. We categorized occupation into 10 groups: general employee; manager; executive manager; public employee, faculty member, or non-profit organization employee; temporary or contract employee; self-employed; small office/home office; agriculture, forestry, or fishing; professional occupation (e.g., lawyer, tax accountant, medical-related work); and other. Job type was classified into three categories: mainly desk work; work mainly involving interpersonal communication; and mainly manual or physical labor.

115

116 Measurement for unemployment

117 We ascertained unemployment as follows. First, the baseline survey included only people
 118 who were employed at the time of response. In the follow-up survey, in answer to the
 119 question “Have you changed your place of work since December 2020?” respondents were
 120 asked to select one of the following six options: “no change”; “I was transferred to another
 121 company”; “I resigned and got a new job right away”; “I stopped working and was
 122 unemployed for a while but am now working”; “I stopped working and started a business
 123 (e.g., managing a company, running a sole proprietorship, or engaging in
 124 self-employment)”; and “I stopped working and am not currently working (including job
 125 seeking).” We defined unemployment as participants choosing one of the following: “I
 126 resigned and got a new job right away”; “I stopped working and was unemployed for a
 127 while but am now working”; “I stopped working and started a business (e.g., managing a
 128 company, running a sole proprietorship, or engaging in self-employment)”; or “I stopped
 129 working and am not currently working (including job seeking).”

130

131 Statistical analysis

132 We determined the odds ratios (ORs) of unemployment for socioeconomic factors using a
 133 multilevel logistic model for the prefecture of residence. The multivariate model was

adjusted for sex and age. We undertook a trend test by conducting the analysis using age, annual household income, and education as continuous variables. We also used the incidence rate of COVID-19 by prefecture as a prefecture-level variable. The multilevel analysis was performed within this incidence rate of COVID-19. We considered *P* values under 0.05 statistically significant. All analyses were conducted using Stata (Stata Statistical Software release SE16.1; StataCorp LLC, College Station, TX, USA).

153

154

155

156

157 **Results**

158 The basic characteristics of the respondents appear in Table 1. There were 11,170 men in
159 the sample, accounting for 56% of the total. The mean age was 48.0 years.

160 Table 2 shows the associations of socioeconomic factors with unemployment: 725
161 (3.6%) workers had experienced unemployment.

162 Multivariate analysis showed that the OR of unemployment associated with sex was
163 1.35 (95% confidence interval [CI], 1.14–1.60) for women compared with men. With
164 increasing age, the OR for unemployment was lower: OR, 0.98; 95% CI, 0.97–0.99; P
165 <0.001 , adjusted for sex. The respective OR and 95% CI figures for the association with
166 marital status were as follows: 1.33 (1.03–1.71) for being married (spouse not working);
167 2.09 (1.65–2.64) for being bereaved or divorced; and 1.29 (1.07–1.56) for being unmarried,
168 compared with being married (spouse working). The respective figures for the association
169 with annual household income were as follows: 4.05 (3.00–5.46) for <2 million yen; 2.12
170 (1.62–2.78) for 2–4 million yen; and 1.46 (1.11–1.93) for 4–6 million yen, compared with
171 >10 million yen. The respective figures for the association with education were as follows:

1.73 (1.12–2.66) for junior high or high school; and 1.83 (1.19–2.83) for vocational school, junior college, or technical school. The respective figures for the association with occupation were as follows: 2.01 (1.63–2.48) for temporary or contract employees; 1.35 (1.02–1.78) for being self-employed; and 3.02 (1.68–5.42) for agriculture, forestry, or fishing, compared with general employees; the figures were 0.56 (0.40–0.79) for public employees, faculty members, or non-profit organization employees. The respective figures for the association with job type were 1.25 (1.04–1.51) for jobs mainly involving interpersonal communication and 1.85 (1.55–2.21) for mainly manual or physical labor, compared with mainly desk work.

195

196 **Discussion**

197 Through a prospective cohort study, this investigation examined the association between
198 socioeconomic factors and subsequent unemployment during COVID-19. Under the
199 pandemic of COVID-19, we found that unemployment was associated with socioeconomic
200 factors such as age, sex, marriage, income, education and occupation.

201 We observed that the risk of unemployment was highest among young people.
202 International Labour Organization (ILO) has reported that worldwide, young people were
203 subjected to the greatest loss of labor opportunities through COVID-19: in 2020, young
204 workers suffered 8.7% job losses compared with 3.7% for adults [13]. The present study
205 conducted in Japan similarly found that young people were more than twice as likely to be
206 unemployed as middle-aged and older workers. This could have been due to the fact that
207 the accommodation and service industry as well as the food and beverage industry (which
208 were most affected by COVID-19) had more young casual workers than other industries
209 [5,14]. In addition, even before the pandemic, there was a high turnover rate of young

people in Japan. The turnover rate within 3 years of graduating from university and entering the workforce was around 30% in 2021 [15]. This is thought to be due to their transition from school to work and still looking for the right job.

By industry and occupation, we found the unemployment rate to be higher among temporary and contract workers, agricultural and forestry workers, and manual laborers. Japan's Labour Force Survey reported that the number of non-regular workers in the country fell sharply under COVID-19 [5]. Many temporary and contract workers were employed in lifestyle-related industries, travel and entertainment services, which were heavily affected by the pandemic [16,17]. Temporary and contract workers are thought to be used to adjust employment and our results clearly confirm this.

We observed a high unemployment rate in the agriculture, forestry, and fisheries sector. The reasons for the high unemployment rate in agriculture are unclear: agriculture is an employment sector that is less susceptible than others to economic fluctuations. One possibility is that the economic downturn in the food service and food industry caused by COVID-19 had an impact on agricultural production [16]. Another explanation for the finding in agriculture, forestry, and fisheries could be that it was reflecting a trend for casual work in Japan: temporary employment during the farming season is common, and over 80% of temporary workers have short-term contracts of under one month [18,19]. A further factor could be that the number of farmers in Japan has been declining annually since

before COVID-19, and the high unemployment we found in agriculture may not have been due solely to the pandemic [20].

We found that women were more likely to be unemployed than men: the OECD has stated that women are also more vulnerable in society [8]. Japan's Labour Force Survey during COVID-19 observed a gender difference in the decline in the number of people in employment: women were more likely to be unemployed [5]. The 2021 survey reported that 68% of people in informal employment were women; many of them worked in the accommodation, catering, and lifestyle-related service industries [5]. In the present study, we found that 14.7% of women (compared with 7.4% of men) were in informal employment.

The unemployment rate was also significantly higher for divorced or bereaved people than with dual-earner households. In economic terms, marriage is held to be a rational behavior that seeks economic gain [21,22]. It has long been pointed out that low-income earners and those with unstable employment are less likely to get married [23,24]. The unmarried participants with their precarious employment situation may become unemployed owing to the pandemic. Also, if the divorced or bereaved had a child, it is possible that they were forced to leave the workplace due to school or after-school care leave, because school closures by the pandemic [25].

With regard to income and education, we observed that the lower the income and

lower the education, the greater was the likelihood of unemployment. It is widely known that such socially vulnerable groups are at higher risk of unemployment [7,9,26]; we found a similar trend during COVID-19. The impact of unemployment on the lives of those with lower incomes is accordingly greater, and they constitute the group in highest need of social support.

Overall, COVID-19 appears to have increased difficulties for a previously vulnerable group. Previous studies have shown that people of lower socioeconomic status are more likely to face difficulties in the event of a pandemic. However, much of the research has focused on the higher risk of contracting infectious diseases and, as a result, being more likely to face problems such as healthcare costs and unemployment [7,27-30]. Our findings suggest that in the event of a major epidemic, resulting in unemployment among vulnerable segments of the labour market, regardless of whether workers themselves are infected. Thus, there is a need for employment and financial support for socially vulnerable groups in the event of a major epidemic.

There are several limitations of this study. First, it was unclear why the participants had experienced unemployment: we did not know whether it was due to the effects of COVID-19, company bankruptcy or financial difficulties, or the participants' voluntary decision to change jobs. Second, this study was conducted as an Internet survey; thus, the generalizability of our results is unclear. It is possible that individuals who were genuinely

penurious did not have Internet access and could not participate in the survey. If such people had taken part in the survey, the bias would have been stronger. We attempted to reduce subject bias as much as possible by sampling by region and occupation based on infection rates. Third, of the 27,036 individuals who participated in the baseline survey, 7095 did not respond to the follow-up survey (non-participation rate, 26%). That may have led to further bias.

Conclusion

We confirmed the relationship between socioeconomic factors and subsequent unemployment in the case of COVID-19. There is a need for widespread, sustained support for socially vulnerable groups in the form of both short-term and long-term vocational training and health care.
